Chapter 1. C Language

This chapter describes the target specific features of the C language, including language extensions that are not standard in ISO-C. For example, pragmas are a way to control the compiler from within the C source.

The TASKING VX-toolset for MCS C compiler fully supports the ISO C99 standard and supports all mandatory language features of the C11 standard, and adds extra possibilities to program the special functions of the target. C11 is the default of the C compiler.

C11 language features

All mandatory ISO C11 language features are supported (ISO/IEC 9899:2011 section 6.10.8.1 Mandatory macros). Furthermore the C compiler supports the following conditional features (ISO/IEC 9899:2011 section 6.10.8.3 Conditional feature macros):

- variable length arrays and variably modified types

Other conditional language features such as threads, as mentioned in section 6.10.8.3 Conditional feature macros and section 6.10.8.2 Environment macros of the ISO/IEC 9899:2011 standard, are not supported. `__STDC_NO_ATOMICS__` and `__STDC_NO_THREADS__` are defined as 1.

Additional language features

In addition to the standard C language, the compiler supports the following:

- extra data types, like `__int72_t`, `__uint72_t` and `__aei_t`
- address space qualifiers
- intrinsic (built-in) functions that result in target specific assembly instructions
- pragmas to control the compiler from within the C source
- predefined macros
- the possibility to use assembly instructions in the C source
- keywords for inlining functions and channel functions
- libraries

All non-standard keywords have two leading underscores (`__`).

In this chapter the target specific characteristics of the C language are described, including the above mentioned extensions.

1.1. Data Types

The C compiler supports the ISO C11 defined data types, and additionally the types `__int72_t`, `__uint72_t` and `__aei_t`. The characteristics of these types are shown in the following table.

The precision describes the number of bits that are used to express a value.

The size is the storage size in bits that a variable of a given C type consumes when it is stored in memory.

The alignment specifies how variables of the given C type are aligned in memory. A memory address is said to be n -bits aligned when the address is a multiple of n bits (where n is a power of 2). The values depend on the data transfer operations as defined by the MCS instruction set architecture.

C Type	Precision	Size	Alignment	Limits
<code>_Bool</code>	1	24	32	0 or 1
<code>char</code>	24	24	32	$[-2^{23}, 2^{23}-1]$
<code>unsigned char</code>	24	24	32	$[0, 2^{24}-1]$
<code>short</code>	24	24	32	$[-2^{23}, 2^{23}-1]$
<code>unsigned short</code>	24	24	32	$[0, 2^{24}-1]$
<code>int</code>	24	24	32	$[-2^{23}, 2^{23}-1]$
<code>unsigned int</code>	24	24	32	$[0, 2^{24}-1]$
<code>enum</code>	24	24	32	$[-2^{23}, 2^{23}-1]$
<code>long</code>	48	48	32	$[-2^{47}, 2^{47}-1]$
<code>unsigned long</code>	48	48	32	$[0, 2^{48}-1]$
<code>long long</code>	72	72	32	$[-2^{71}, 2^{71}-1]$
<code>unsigned long long</code>	72	72	32	$[0, 2^{72}-1]$
<code>__int72_t</code>	72	72	32	$[-2^{71}, 2^{71}-1]$
<code>__uint72_t</code>	72	72	32	$[0, 2^{72}-1]$
<code>float</code> (23-bit mantissa)	32	48	32	$[-3.402E+38, -1.175E-38]$ $[+1.175E-38, +3.402E+38]$
<code>double</code> <code>long double</code> (52-bit mantissa)	64	72	32	$[-1.797E+308, -2.225E-308]$ $[+2.225E-308, +1.797E+308]$
<code>pointer to data or function</code> <code>pointer to ARU, AEI, OREG,</code> <code>XOREG or WXREG</code>	24	24	32	$[0, 2^{24}-1]$
<code>__aei_t</code> <code>__mcs_aei_t</code>	32	32	32	$[0, 2^{32}-1]$

A byte is defined as the size of a `char`, so a byte contains 24 bits.

Data type `__aei_t` is a storage type to interface on the AEI Bus Master Interface. Arithmetic operations applied on this data type result in either 32-bit unsigned behavior or undefined behavior. `__mcs_aei_t` is an alias of `__aei_t` for use with the `__mcs_intrinsics`.

Data types that consist of multiple words are allocated with the least significant word at the lowest memory address (little-endian). The contents of the upper RDW-W bits of a memory location are undefined, except for objects of type `__aei_t`.

Arrays

Arrays are aligned according to the alignment of its element type.

Structures and unions

The alignment of structures and unions is equivalent with the most restrictive alignment of their members.

A structure or union is padded to the alignment of its most restrictive member.

Bit-fields

Individual bit-fields cannot exceed 24 bits in width. The allowed bit-field fundamental data types are `_Bool`, `(un)signed char`, `(un)signed short`, `(un)signed int` and `enum`. The maximum bit-field size is equal to that of the type's size. For the bit-field types the same rules regarding to alignment and signed-ness apply as specified for the fundamental data types. Plain `int` bit-fields (without the `signed` or `unsigned` type modifier) are `unsigned`. In addition, the following rules apply:

- The first bit-field is stored at the least significant bits. Subsequent bit-fields will fill the higher significant bits.
- A bit-field of a particular type cannot cross a boundary as is specified by its maximum width. For example, a bit-field of type `short` cannot cross a 24-bit boundary.
- Bit-fields share a storage unit with other bit-field members if and only if there is sufficient space in the storage unit. Adjacent bit-fields are packed together with no padding in between, except as required for the special case of a zero-width bit-field.
- An unnamed bit-field creates a gap that has the size of the specified width.
- As a special case, an unnamed bit-field having width 0 (zero) prevents any further bit-fields from residing in the storage unit corresponding to the type of the zero-width bit-field (a zero-width bit-field, as specified by ISO C, forces alignment to a storage unit boundary, which for MCS is 32 bits).

Bit-fields are always allocated beginning with the next available bit in the structure or union. No alignment padding is inserted, except for the cases noted. In the following example therefore, padding will be inserted in bits [31:9] of the first 32 bits to complete a full 32-bit word in memory. The 17-bit bit-field `f17` will occupy positions [16:0] of the second word in memory. Padding will be inserted in bits [31:17] to complete a full word, and the structure will be 32-bit aligned.

```
struct {
    int f1: 5;
    int f2: 4;
    // padding ...
    int f17: 17;
    // padding ...
};
```

1.1.1. Floating-point Types

The IEEE Std 754-2008 binary 32 format is used for C type `float` and the binary 64 format is used for C types `double` and `long double`.

The first word in the tables below is the most significant word. The last word in the tables is the least significant word.

float

Bit number	31 0	31 0
Binary encoding	----.---.0000.0000.0000.0000.eeee.eeee	----.---. sssssss . rrrrrrrrr . rrrrrrrrr . rrrrrrrrr . rrrrrrrrr . rrrrrrrrr

double / long double

Bit number	31 ----- 0	31 ----- 0	31 ----- 0
Binary encoding	-----,-----,0000.0000,eeee.eeee.eeee.mmmmm	-----,-----,mmmmmm,mmmmmm,mmmmmm,mmmmmm,mmmmmm,mmmmmm	-----,-----,mmmmmm,mmmmmm,mmmmmm,mmmmmm,mmmmmm,mmmmmm

s = sign bit, m = mantissa bit, e = exponent bit, - = undefined

1.2. Special Function Registers

You can access the MCS special function registers (SFRs) directly from your C source.

The special function register set (SFR_REG) consists of the following registers:

```

STA          (status register)
CTRG        (clear trigger bits register)
STRG        (set trigger bits register)
TBU_TS0     (TBU timestamp TS0 register)
TBU_TS1     (TBU timestamp TS1 register)
TBU_TS2     (TBU timestamp TS2 register)
DSTA        (DPLL status register)
DSTAX       (DPLL extended status register)
GMI0        (GTM Module Interrupt 0 register)
GMI1        (GTM Module Interrupt 1 register)

```

The general purpose registers R0 .. R7 and RS0 .. RS7, as well as registers MHB and ACB are not accessible.

The STA flags N, V, Z and CY are compiler resources, you cannot use them. The CAT, CWT and SAT flags are used by intrinsic functions.

The SFRs are defined in `.sfr` files. The files are located in the `sfr` subdirectory of the standard include directory. The files are named `regcpu.sfr`, where `cpu` is the CPU specified with the [control program option](#) `--cpu`.

For example from `regtc39xb.sfr`:

```
#define STA (*(__oreg volatile unsigned int *)0x08)
```

The compiler includes this register file if you specify [option](#) `--include-file=sfr/regtc39xb.sfr`

Example of accessing an SFR from C:

```

if ( (CTRG & 0x8) !=0 )
{
    TBU_TS1 = 0x7;
}

```

Note that indirect access to SFRs might not work if your hardware is configured by a memory protection unit in such a way that self-modifying code is not allowed. So, try to avoid working with pointers to SFRs. The compiler issues a warning (W798) and an informational message (I852).

```
#include __SFRFILE__(tc39xb)

int read_sfr( __oreg volatile unsigned int * p )
{
    *p = 10;      // W789 and I852
    return *p;   // W789 and I852
}

int main( void )
{
    read_sfr( & STA      );
    read_sfr( & TBU_TS0 );
    __wurmx( & TBU_TS0, 2, 2 );
    return 0;
}
```

1.3. Address Space Qualifiers

The C compiler supports several address space qualifiers for the definition of SFRs and intrinsic functions.

Address Space Qualifier	Applicable to Registers	Remarks
<code>__oreg</code>	STA, CTRG, STRG, TBU_TS0, TBU_TS1, TBU_TS2	The OREG register set consists of R0 . . R7, STA, ACB, CTRG, STRG, TBU_TS0, TBU_TS1, TBU_TS2 and MHB. The Rx registers, ACB and MHB are omitted from <code>__oreg</code> since these registers are used by the compiler.
<code>__xoreg</code>	STA, CTRG, STRG, TBU_TS0, TBU_TS1, TBU_TS2, GMI0, GMI1, DSTA, DSTAX	The XOREG register set consists of the OREG register set plus RS0 . . RS7, GMI0, GMI1, DSTA and DSTAX. Address space <code>__oreg</code> is nested into <code>__xoreg</code> . The RSx registers are omitted from <code>__xoreg</code> .
<code>__wxreg</code>	STA, CTRG, STRG, TBU_TS0, TBU_TS1, TBU_TS2, GMI0, GMI1, DSTA, DSTAX	The WXREG register set consists of the OREG register set plus GMI0, GMI1, DSTA and DSTAX.
<code>__aei</code>		To facilitate checking of addresses passed to the bus master interface intrinsics.
<code>__aru</code>		To facilitate checking of addresses passed to the blocking and non-blocking ARU read intrinsics.

You can combine multiple address space qualifiers to specify that a register is located in multiple address spaces. For example:

```
#define DSTA (*(volatile __xoreg __wxreg *)0x1a) /* DSTA belongs to XOREG as well as
                                                to WXREG */
#define SOME_XOREG (*(volatile __xoreg )0x..) /* SOME_XOREG only belongs to XOREG */
#define SOME_WXREG (*(volatile __wxreg *)0x..) /* SOME_WXREG only belongs to WXREG */
```

Because of the `__aei` qualifier, you can access an SFR on the AEI bus master interface also without using intrinsics.

For example, `CMU_CLK_EN` is defined in `regtc39xb.sfr` as:

```
#define CMU_CLK_EN (*(__aei volatile __aei_t *)0x7000)
```

You can access it in your C source:

```
CMU_CLK_EN = 8;
```

The compiler generates the following assembly:

```
movl r5,#8
movl mhb,#0
bwr r5,28672
```

`__aru` qualified SFRs are only accessible through intrinsics.

See [Section 1.2, *Special Function Registers*](#) and [Section 1.9.7, *Intrinsic Functions*](#) for more information.

Pointer conversions

The compiler supports the following pointer conversions (casts):

```
__oreg          --> __xoreg
__oreg          --> __wxreg
__xoreg __wxreg --> __wxreg
__xoreg __wxreg --> __xoreg
```

1.4. Shift JIS Kanji Support

In order to allow for Japanese character support on non-Japanese systems (like PCs), you can use the Shift JIS Kanji Code standard. This standard combines two successive ASCII characters to represent one Kanji character. A valid Kanji combination is only possible within the following ranges:

- First (high) byte is in the range 0x81-0x9f or 0xe0-0xef.
- Second (low) byte is in the range 0x40-0x7e or 0x80-0xfc

Compiler option `-Ak` enables support for Shift JIS encoded Kanji multi-byte characters in strings and (wide) character constants. Without this option, encodings with 0x5c as the second byte conflict with the

TASKING VX-toolset for MCS User Guide

use of the backslash ('\') as an escape character. Shift JIS in comments is supported regardless of this option.

Note that Shift JIS also includes Katakana and Hiragana.

Example:

```
// Example usage of Shift JIS Kanji
// Do not switch off option -Ak
// At the position of the italic text you can
// put your Shift JIS Kanji code
int i; // put Shift JIS Kanji here
char c1;
char c2;
unsigned int ui;
const char mes[]="put Shift JIS Kanji here";
const unsigned int ar[5]={'K','a','n',
                          'j','i'};
                          // 5 Japanese array

void main(void)
{
    i=(int)c1;
    i++; /* put Shift JIS Kanji here\
          continuous comment */
    c2=mes[9];
    ui=ar[0];
}
```

1.5. Using Assembly in the C Source: __asm()

With the keyword `__asm()` you can use assembly instructions in the C source and pass C variables as operands to the assembly code.

It is recommended to use constructs in C or use [intrinsic functions](#) instead of `__asm()`. Be aware that C modules that contain assembly are not portable and harder to compile in other environments.

The compiler does not interpret assembly blocks but passes the assembly code to the assembly source file; they are regarded as a black box. So, it is your responsibility to make sure that the assembly block is syntactically correct. Possible errors can only be detected by the assembler.

You need to tell the compiler exactly what happens in the inline assembly code because it uses that for code generation and optimization. The compiler needs to know exactly which registers are written and which registers are only read. For example, if the inline assembly writes to a register from which the compiler assumes that it is only read, the generated code after the inline assembly is based on the fact that the register still contains the same value as before the inline assembly. If that is not the case the results may be unexpected. Also, an inline assembly statement using multiple input parameters may be assigned the same register if the compiler finds that the input parameters contain the same value. As long as this register is only read this is not a problem.

General syntax of the `__asm` keyword

```
__asm( "instruction_template"
      [ : output_param_list
      [ : input_param_list
      [ : register_reserve_list]] ] );
```

<i>instruction_template</i>	Assembly instructions that may contain parameters from the input list or output list in the form: <code>%parm_nr[.regnum]</code>
<code>%parm_nr</code>	Parameter number in the range 0 .. 9.
<i>output_param_list</i>	<code>[["=[&]constraint_char"(C_expression)],...]</code>
<i>input_param_list</i>	<code>[["constraint_char"(C_expression)],...]</code>
<code>&</code>	Says that an output operand is written to before the inputs are read, so this output must not be the same register as any input.
<i>constraint_char</i>	Constraint character: the type of register to be used for the <i>C_expression</i> . See the table below.
<i>C_expression</i>	Any C expression. For output parameters it must be an lvalue, that is, something that is legal to have on the left side of an assignment.
<i>register_reserve_list</i>	<code>["register_name"],...</code>
<i>register_name</i>	Name of the register you want to reserve. For example because this register gets clobbered by the assembly code. The compiler will not use this register for inputs or outputs. Note that reserving too many registers can make register allocation impossible.

Specifying registers for C variables

With a *constraint character* you specify the register type for a parameter.

You can reserve the registers that are used in the assembly instructions, either in the parameter lists or in the reserved register list (*register_reserve_list*). The compiler takes account of these lists, so no unnecessary register saves and restores are placed around the inline assembly instructions.

Constraint character	Type	Operand	Remark
r	general purpose register	r0 .. r6	Input and output constraint.
s	general purpose register and mirror	r0 .. r6, and rs0 .. rs7 when <code>option --extended-registers</code> is used	Input and output constraint.
<i>number</i>	type of operand it is associated with	same as <code>%number</code>	Input constraint only. The <i>number</i> must refer to an output parameter. Indicates that <code>%number</code> and <i>number</i> are the same register.

If an input parameter is modified by the inline assembly then this input parameter must also be added to the list of output parameters (see [Example 6](#)). If this is not the case, the resulting code may behave differently than expected since the compiler assumes that an input parameter is not being changed by the inline assembly.

Loops and conditional jumps

The compiler does not detect loops with multiple `__asm()` statements or (conditional) jumps across `__asm()` statements and will generate incorrect code for the registers involved.

If you want to create a loop with `__asm()`, the whole loop must be contained in a single `__asm()` statement. The same counts for (conditional) jumps. As a rule of thumb, all references to a label in an `__asm()` statement must be in that same statement. You can use numeric labels for these purposes.

Example 1: no input or output

A simple example without input or output parameters. You can use any instruction or label. When it is required that a sequence of `__asm()` statements generates a contiguous sequence of instructions, then they can be best combined to a single `__asm()` statement. Compiler optimizations can insert instruction(s) in between `__asm()` statements. Use newline characters `'\n'` to continue on a new line in a `__asm()` statement. For multi-line output, use tab characters `'\t'` to indent instructions.

```
__asm( "nop\n"
      "\tnop" );
```

Example 2: using output parameters

Assign the result of inline assembly to a variable. A register is chosen for the parameter because of the constraint `s`; the compiler decides which register is best to use. The `%0` in the instruction template is replaced with the name of the variable.

```
int read_acb( void )
{
    int out;

    __asm( "MOV    %0,acb"
          : "=s" (out) );

    return out;
}
```

Generated assembly code:

```
MOV    r2,acb ; r2 is chosen as output register
```

Example 3: using input parameters

The preferred use is to use intrinsics, but for illustrating purposes the following example performs a write access on the bus master interface. A register is chosen for the parameter because of the constraint `r`;

the compiler decides which register is best to use. The %0 in the instruction template is replaced with the name of this register. The compiler generates code to move the input variable to the input register. Because there are no output parameters, the output parameter list is empty. Only the colon has to be present.

```
void writebm( int in )
{
    __asm( "BWR    %0,#256"
          :
          : "r" (in) );
}
int main(void)
{
    writebm(1234);
    return 1;
}
```

Generated assembly code:

```
.sdecl  '.mcstext.example3.writebm'
.sect   '.mcstext.example3.writebm'
.global writebm
.align  4
writebm: .type func
        BWR    r2,#256
        ret

.sdecl  '.mcstext.example3.main'
.sect   '.mcstext.example3.main'
.global main
.align  4
main:   .type func
        movl   r2,#1234
        call  writebm
        movl   r2#1
        ret
```

Example 4: using input and output parameters

Assign one C variable to another variable. Registers are necessary for the input and output parameters (constraint s, %0 for out, %1 for in in the instruction template). The compiler generates code to move the input expression into the input register.

```
int in=5;

int movvar( void )
{
    int out;

    __asm( "MOV    %0,%1"
          : "=s" (out)
          : "s" (in) );
}
```

```
    return out;
}
```

Generated assembly code:

```
movvar: .type func
        mrd   r5,in
        MOV   r2,r5
        ret
```

Example 5: reserving registers

Sometimes an instruction knocks out certain specific registers. The most common example of this is a function call, where the called function is allowed to do whatever it likes with some registers. If this is the case, you can list specific registers that get clobbered by an operation after the inputs.

Same as *Example 4*, but now register `r5` is a reserved register. You can do this by adding a reserved register list (`: "r5"`). As you can see in the generated assembly code, register `r5` is not used (the register used is `r4`).

```
int in=5;

int movvar( void )
{
    int out;

    __asm( "MOV   %0,%1"
          : "=s" (out)
          : "s" (in)
          : "r5" );
    return out;
}
```

Generated assembly code:

```
movvar: .type func
        mrd   r4,in
        MOV   r2,r4
        ret
```

Example 6: use the same register for input and output

As input constraint you can use a number to refer to an output parameter. This tells the compiler that the same register can be used for the input and output parameter. When the input and output parameter are the same C expression, these will effectively be treated as if the input parameter is also used as output. In that case it is allowed to write to this register. For example:

```
inline int foo(int par1, int par2)
{
    int retvalue;
```

```

__asm(
    "SHL    %1,#2\n\t"
    "ADD    %2,%1\n\t"
    "MOV    %0,%2"
    : "&s" (retvalue), "=s" (par1), "=s" (par2)
    : "1" (par1), "2" (par2)
);
return retvalue;
}

int result;

void func(void)
{
    result = foo(1000,1000);
}

```

In this example the "1" constraint for the input parameter `par1` refers to the output parameter `par1`, and similar for the "2" constraint and `par2`. In the inline assembly `%1 (par1)` and `%2 (par2)` are written. This is allowed because the compiler is aware of this.

This results in the following generated assembly code:

```

movl   r5,#1000
mov    r4,r5

SHL    r5,#2
ADD    r4,r5
MOV    r3,r4
mwr   r3,result

```

However, when the inline assembly would have been as given below, the compiler would have assumed that `%1 (par1)` and `%2 (par2)` were read-only. Because of the `inline` keyword the compiler knows that `par1` and `par2` both contain 1000. Therefore the compiler can optimize and assign the same register to `%1` and `%2`. This would have given an unexpected result.

```

__asm(
    "SHL    %1,#2\n\t"
    "ADD    %2,%1\n\t"
    "MOV    %0,%2"
    : "&s" (retvalue)
    : "s" (par1), "s" (par2)
);

```

Generated assembly code:

```

movl   r5,#1000

SHL    r5,#2
ADD    r5,r5           ; same register, but is expected read-only

```

```
MOV    r4,r5
mwr   r4,result    ; contains unexpected result
```

1.6. Attributes

You can use the keyword `__attribute__` to specify special attributes on declarations of variables, functions, types, and fields.

Syntax:

```
__attribute__((name,...))
```

or:

```
__name__
```

The second syntax allows you to use attributes in header files without being concerned about a possible macro of the same name. This second syntax is only possible on attributes that do not already start with an underscore. For example, you may use `__noreturn__` instead of `__attribute__((noreturn))`.

alias("symbol")

You can use `__attribute__((alias("symbol")))` to specify that the function declaration appears in the object file as an alias for another symbol. For example:

```
void __f() { /* function body */; }
void f() __attribute__((weak, alias("__f")));
```

declares 'f' to be a weak alias for '__f'.

const

You can use `__attribute__((const))` to specify that a function has no side effects and will not access global data. This can help the compiler to optimize code. See also attribute [pure](#).

The following kinds of functions should not be declared `__const__`:

- A function with pointer arguments which examines the data pointed to.
- A function that calls a non-const function.

export

You can use `__attribute__((export))` to specify that a variable/function has external linkage and should not be removed. During MIL linking, the compiler treats external definitions at file scope as if they were declared `static`. As a result, unused variables/functions will be eliminated, and the alias checking algorithm assumes that objects with static storage cannot be referenced from functions outside the current module. During MIL linking not all uses of a variable/function can be known to the compiler. For example when a variable is referenced in an assembly file or a (third-party) library. With the `export` attribute the compiler will not perform optimizations that affect the unknown code.

```
int i __attribute__((export)); /* 'i' has external linkage */
```

flatten

You can use `__attribute__((flatten))` to force inlining of all function calls in a function, including nested function calls.

Unless inlining is impossible or disabled by `__attribute__((noinline))` for one of the calls, the generated code for the function will not contain any function calls.

format(type, arg_string_index, arg_check_start)

You can use `__attribute__((format(type, arg_string_index, arg_check_start)))` to specify that functions take `printf`, `scanf`, `strftime` or `strfmon` style arguments and that calls to these functions must be type-checked against the corresponding format string specification.

type determines how the format string is interpreted, and should be `printf`, `scanf`, `strftime` or `strfmon`.

arg_string_index is a constant integral expression that specifies which argument in the declaration of the user function is the format string argument.

arg_check_start is a constant integral expression that specifies the first argument to check against the format string. If there are no arguments to check against the format string (that is, diagnostics should only be performed on the format string syntax and semantics), *arg_check_start* should have a value of 0. For `strftime`-style formats, *arg_check_start* must be 0.

Example:

```
int foo(int i, const char * my_format, ...) __attribute__((format(printf, 2, 3)));
```

The format string is the second argument of the function `foo` and the arguments to check start with the third argument.

leaf

You can use `__attribute__((leaf))` to specify that a function is a leaf function. A leaf function is an external function that does not call a function in the current compilation unit, directly or indirectly. The attribute is intended for library functions to improve dataflow analysis. The attribute has no effect on functions defined within the current compilation unit.

malloc

You can use `__attribute__((malloc))` to improve optimization and error checking by telling the compiler that:

- The return value of a call to such a function points to a memory location or can be a null pointer.
- On return of such a call (before the return value is assigned to another variable in the caller), the memory location mentioned above can be referenced only through the function return value; e.g., if the pointer value is saved into another global variable in the call, the function is not qualified for the `malloc` attribute.

- The lifetime of the memory location returned by such a function is defined as the period of program execution between a) the point at which the call returns and b) the point at which the memory pointer is passed to the corresponding deallocation function. Within the lifetime of the memory object, no other calls to malloc routines should return the address of the same object or any address pointing into that object.

noinline

You can use `__attribute__((noinline))` to prevent a function from being considered for inlining. Same as keyword `__noinline` or `#pragma noinline`.

always_inline

With `__attribute__((always_inline))` you force the compiler to inline the specified function, regardless of the optimization strategy of the compiler itself. Same as keyword `inline` or `#pragma inline`.

noreturn

Some standard C function, such as `abort` and `exit` cannot return. The C compiler knows this automatically. You can use `__attribute__((noreturn))` to tell the compiler that a function never returns. For example:

```
void fatal() __attribute__((noreturn));

void fatal( /* ... */ )
{
    /* Print error message */
    exit(1);
}
```

The function `fatal` cannot return. The compiler can optimize without regard to what would happen if `fatal` ever did return. This can produce slightly better code and it helps to avoid warnings of uninitialized variables.

protect

You can use `__attribute__((protect))` to exclude a variable/function from the duplicate/unreferenced section removal optimization in the linker. When you use this attribute, the compiler will add the "protect" section attribute to the symbol's section. Example:

```
int i __attribute__((protect));
```

Note that the `protect` attribute will not prevent the compiler from removing an unused variable/function (see the `used` symbol attribute).

pure

You can use `__attribute__((pure))` to specify that a function has no side effects, although it may read global data. Such pure functions can be subject to common subexpression elimination and loop optimization. See also attribute `const`.

section("section_name")

You can use `__attribute__((section("name")))` to specify that a function must appear in the object file in a particular section. For example:

```
extern void foobar(void) __attribute__((section("bar")));
```

puts the function `foobar` in the section named `bar`.

See also `#pragma section`.

used

You can use `__attribute__((used))` to prevent an unused symbol from being removed, by both the compiler and the linker. Example:

```
static const char copyright[] __attribute__((used)) = "Copyright 2019 TASKING BV";
```

When there is no C code referring to the `copyright` variable, the compiler will normally remove it. The `__attribute__((used))` symbol attribute prevents this. Because the linker should also not remove this symbol, `__attribute__((used))` implies `__attribute__((protect))`.

unused

You can use `__attribute__((unused))` to specify that a variable or function is possibly unused. The compiler will not issue warning messages about unused variables or functions.

weak

You can use `__attribute__((weak))` to specify that the symbol resulting from the function declaration or variable must appear in the object file as a weak symbol, rather than a global one. This is primarily useful when you are writing library functions which can be overwritten in user code without causing duplicate name errors.

See also `#pragma weak`.

1.7. Pragmas to Control the Compiler

Pragmas are keywords in the C source that control the behavior of the compiler. Pragmas overrule compiler options. Put pragmas in your C source where you want them to take effect. Unless stated otherwise, a pragma is in effect from the point where it is included to the end of the compilation unit or until another pragma changes its status.

The syntax is:

```
#pragma [label:]pragma-spec pragma-arguments [on | off | default | restore]
```

or:

```
_Pragma( "[label:]pragma-spec pragma-arguments [on | off | default | restore]" )
```

Some pragmas can accept the following special arguments:

on	switch the flag on (same as without argument)
off	switch the flag off
default	set the pragma to the initial value
restore	restore the previous value of the pragma

Examples:

```
// by default all warnings are shown

#pragma warning 535           // disable W535
#pragma warning 530         // also disable W530
const char var_1 = 0x5678; // W530 is not shown
var_2;                      // W535 is not shown
#pragma warning restore    // restore one level, only W535 is disabled
const char var_3 = 0x56789; // W530 is shown
#pragma warning default    // back to default, all warnings are shown
var_4;                    // W535 is shown
```

Label pragmas

Some pragmas support a label prefix of the form "*label*:" between `#pragma` and the pragma name. Such a label prefix limits the effect of the pragma to the statement following a label with the specified name. The `restore` argument on a pragma with a label prefix has a special meaning: it removes the most recent definition of the pragma for that label.

You can see a label pragma as a kind of macro mechanism that inserts a pragma in front of the statement after the label, and that adds a corresponding `#pragma ... restore` after the statement.

Compared to regular pragmas, label pragmas offer the following advantages:

- The pragma text does not clutter the code, it can be defined anywhere before a function, or even in a header file. So, the pragma setting and the source code are uncoupled. When you use different header files, you can experiment with a different set of pragmas without altering the source code.

- The pragma has an implicit end: the end of the statement (can be a loop) or block. So, no need for `pragma restore / endoptimize` etc.

Example:

```
#pragma lab1:optimize P

volatile int v;

void f( void )
{
    int i, a;

    a = 42;

lab1: for( i=1; i<10; i++ )
    {
        /* the entire for loop is part of the pragma optimize */
        a += i;
    }
    v = a;
}
```

Supported pragmas

The compiler recognizes the following pragmas, other pragmas are ignored. On the command line you can use **`cmcs --help=pragmas`** to get a list of all supported pragmas. Pragmas marked with (*) support a label prefix.

STDC FP_CONTRACT [on | off | default | restore] (*)

This pragma is defined in ISO C99/C11. With this pragma you can control the **`+contract`** flag of C compiler option **`--fp-model`**.

alias *symbol=defined_symbol*

Define *symbol* as an alias for *defined_symbol*. It corresponds to a **`.ALIAS`** directive at assembly level. The *symbol* should not be defined elsewhere, and *defined_symbol* should be defined with static storage duration (not extern or automatic).

boolean [on | off | default | restore] (*)

This pragma is used to mark the macros "false" and "true" from the library header file `stdbool.h` as "essentially BOOLEAN", which is a concept from the MISRA C:2012 standard.

extension isuffix [on | off | default | restore] (*)

Enables a language extension to specify imaginary floating-point constants. With this extension, you can use an "i" suffix on a floating-point constant, to make the type `_Imaginary`.

```
float 0.5i
```

extern symbol

Normally, when you use the C keyword `extern`, the compiler generates an `.EXTERN` directive in the generated assembly source. However, if the compiler does not find any references to the `extern` symbol in the C module, it optimizes the assembly source by leaving the `.EXTERN` directive out.

With this pragma you can force an external reference (`.EXTERN` assembler directive), even when the *symbol* is not used in the module.

fp_negzero [on | off | default | restore] (*)

With this pragma you can control the **+negzero** flag of C compiler option `--fp-model`.

fp_nonan [on | off | default | restore] (*)

With this pragma you can control the **+nonan** flag of C compiler option `--fp-model`.

fp_rewrite [on | off | default | restore] (*)

With this pragma you can control the **+rewrite** flag of C compiler option `--fp-model`.

inline / noinline / smartinline [default | restore] (*)

See Section 1.9.5, *Inlining Functions: inline*.

inline_max_incr {value | default | restore} (*)

inline_max_size {value | default | restore} (*)

With these pragmas you can control the automatic function inlining optimization process of the compiler. It has effect only when you have enable the inlining optimization (C compiler option `--optimize=+inline`).

See C compiler options `--inline-max-incr / --inline-max-size`.

macro / nomacro [on | off | default | restore] (*)

Turns macro expansion on or off. By default, macro expansion is enabled.

message "message" ...

Print the message string(s) on standard output.

nomisrac [nr,...] [default | restore] (*)

Without arguments, this pragma disables MISRA C checking. Alternatively, you can specify a comma-separated list of MISRA C rules to disable.

See C compiler option `--misrac` and Section 3.6.2, *C Code Checking: MISRA C*.

optimize [*flags*] / **endoptimize** [default | restore] (*)

You can overrule the C compiler option `--optimize` for the code between the pragmas `optimize` and `endoptimize`. The pragma works the same as C compiler option `--optimize`.

See Section 3.5, *Compiler Optimizations*.

section [*type=*][*format_string*][,...] / **endsection** [default | restore] (*)

Rename sections by adding a *format_string* to all section names specified with *.type*, or restore default section naming. If you specify only a *format_string* (without a type), the suffix is added to all section names. See Section 1.10, *Section Naming*, C compiler option `--rename-sections` and assembler directive `.SDECL` for more information.

source / **nosource** [on | off | default | restore] (*)

With these pragmas you can choose which C source lines must be listed as comments in assembly output.

See C compiler option `--source`.

stdinc [on | off | default | restore] (*)

This pragma changes the behavior of the `#include` directive. When set, the C compiler options `--include-directory` and `--no-stdinc` are ignored.

tradeoff *level* [default | restore] (*)

Specify tradeoff between speed (0) and size (4). See C compiler option `--tradeoff`

unroll_factor *value* / **endunroll_factor** [default | restore] (*)

Specify how many times the following loop should be unrolled, if possible. At the end of the loop use `endunroll_factor`.

See C compiler option `--unroll-factor`.

warning [*number*,...] [default | restore] (*)

With this pragma you can disable warning messages. If you do not specify a warning number, all warnings will be suppressed.

weak symbol

Mark a symbol as "weak" (`.WEAK` assembler directive). The symbol must have external linkage, which means a global or external object or function. A static symbol cannot be declared weak.

A weak external reference is resolved by the linker when a global (or weak) definition is found in one of the object files. However, a weak reference will not cause the extraction of a module from a library to resolve the reference. When a weak external reference cannot be resolved, the null pointer is substituted.

A weak definition can be overruled by a normal global definition. The linker will not complain about the duplicate definition, and ignore the weak definition.

1.8. Predefined Preprocessor Macros

The TASKING C compiler supports the predefined macros as defined in the table below. The macros are useful to create conditional C code.

Macro	Description
<code>__BUILD__</code>	Identifies the build number of the compiler in the format <code>yymmddqq</code> (year, month, day and quarter in UTC).
<code>__CMCS__</code>	Identifies the compiler. You can use this symbol to flag parts of the source which must be recognized by the TASKING cmcs compiler only. It expands to 1.
<code>__CORE__</code>	Expands to a string with the core name depending on the option <code>--core=core</code> . The dots '.' are removed from the core name. For example, if <code>--core=mcs3.0</code> is specified, the symbol <code>__CORE__</code> expands to <code>mcs30</code> .
<code>__CORE_core__</code>	A symbol is defined depending on the option <code>--core=core</code> . The <i>core</i> is converted to uppercase and the dots '.' are removed. For example, if <code>--core=mcs3.0</code> is specified, the symbol <code>__CORE_MCS30__</code> is defined. When no <code>--core</code> is supplied, the compiler defines <code>__CORE_MCS31__</code> .
<code>__DATE__</code>	Expands to the compilation date: "mmm dd yyyy".
<code>__DOUBLE_FP__</code>	Expands to 1 if you used option <code>--fp-model=float</code> , otherwise unrecognized as macro.
<code>__FILE__</code>	Expands to the current source file name.
<code>__HAS_FLOAT_BUILTINS__</code>	Expands to 1.
<code>__LINE__</code>	Expands to the line number of the line where this macro is called.
<code>__LITTLE_ENDIAN__</code>	Expands to 1. The processor accesses data in little-endian.
<code>__MISRAC_VERSION__</code>	Expands to the MISRA C version used 1998, 2004 or 2012 (option <code>--misrac-version</code>). The default is 2004.
<code>__PROF_ENABLE__</code>	Expands to 1 if profiling is enabled, otherwise expands to 0.
<code>__REVISION__</code>	Expands to the revision number of the compiler. Digits are represented as they are; characters (for prototypes, alphas, betas) are represented by -1. Examples: <code>v1.0r1 -> 1</code> , <code>v1.0rb -> -1</code>
<code>__SFRFILE__(cpu)</code>	If control program option <code>--cpu=cpu</code> is specified, this macro expands to the filename of the used SFR file, including the pathname and the < >. The <i>cpu</i> is the argument of the macro. For example, if <code>--cpu=tc39xb</code> is specified, the macro <code>__SFRFILE__(__CPU__)</code> expands to <code>__SFRFILE__(tc39xb)</code> , which expands to <code><sfr/regtc39xb.sfr></code> .
<code>__SINGLE_FP__</code>	Expands to 1 if you used option <code>--fp-model=float</code> (Treat 'double' as 'float'), otherwise unrecognized as macro.

Macro	Description
<code>__STDC__</code>	Identifies the level of ANSI standard. The macro expands to 1 if you set option <code>--language</code> (Control language extensions), otherwise expands to 0.
<code>__STDC_HOSTED__</code>	Always expands to 0, indicating the implementation is not a hosted implementation.
<code>__STDC_NO_ATOMICS__</code>	(C11 only) Expands to 1 to indicate that this implementation does not support atomic types and the <code>stdatomic.h</code> header file.
<code>__STDC_NO_THREADS__</code>	(C11 only) Expands to 1 to indicate that this implementation does not support the <code>threads.h</code> header file.
<code>__STDC_VERSION__</code>	Identifies the ISO-C version number. Expands to 201112L for ISO C11, 199901L for ISO C99 or 199409L for ISO C90.
<code>__TASKING__</code>	Identifies the compiler as a TASKING compiler. Expands to 1 if a TASKING compiler is used.
<code>__TIME__</code>	Expands to the compilation time: "hh:mm:ss"
<code>__VERSION__</code>	Identifies the version number of the compiler. For example, if you use version 2.1r1 of the compiler, <code>__VERSION__</code> expands to 2001 (dot and revision number are omitted, minor version number in 3 digits).
<code>__VX__</code>	Identifies the VX-toolset C compiler. Expands to 1.

Example

```
#ifdef __CORE_MCS31__
/* this part is only compiled for core mcs3.1 */
...
#endif
```

1.9. Functions

1.9.1. Calling Convention

Parameter passing

A lot of execution time of an application is spent transferring parameters between functions. The fastest parameter transport is via registers. Therefore, function parameters are first passed via registers. If no more registers are available for a parameter, the compiler pushes parameters on the stack.

Registers available for parameter passing are r2, r3, r4 and r5. The parameters are loaded sequentially into the parameter registers. For each parameter the next unused register (pair) is selected. If fewer (or no) registers are needed, the unneeded registers are not loaded and will contain undefined values on entry to the called function. Up to four arithmetic types or four pointers can be passed this way.

The following table specifies which registers are used to pass an object of a specific type to a function.

Type	Registers used for parameters
_Bool	r2, r3, r4 or r5
(unsigned) char	r2, r3, r4 or r5
(unsigned) short	r2, r3, r4 or r5
(unsigned) int	r2, r3, r4 or r5
(unsigned) long	r2r3, r3r4 or r4r5
(unsigned) long long	r2r3r4 or r3r4r5
__int72_t	r2r3r4 or r3r4r5
__uint72_t	r2r3r4 or r3r4r5
float	r2r3, r3r4 or r4r5
(long) double	r2r3r4 or r3r4r5
pointer to function / data / ARU / AEI / OREG / XOREG / WXREG	r2, r3, r4 or r5
struct / union* (size 24-bits)	r2, r3, r4 or r5
struct / union* (size 48-bits)	r2r3, r3r4 or r4r5
struct / union* (size 72-bits)	r2r3r4 or r3r4r5

* Small struct/union types are passed in registers, except when any of the members has the `__aei_t` type.

Only when the parameters do not fit in the four registers provided for parameter passing, or when the object is an aggregate type that cannot be passed in registers, or has the `__aei_t` type, the caller allocates stack space for the parameters in its stack frame. It allocates only enough space to hold the parameters that do not fit into registers. The space that holds the parameters is called the argument passing area (APA).

Examples:

```
void func1( int i, char * p, char c );      /* r2 r3 r4 */
void func2( int i1, double d, int i2 );   /* r2 r3r4r5 stack */
void func3( char c1, char c2, char c3[] ); /* r2 r3 r4 */
void func4( double d1, int i1, double d2, int i2 );
                                           /* r2r3r4 r5 stack stack */
```

Variable argument lists

Parameters that are passed to a function in the variable argument list are always passed in the argument passing area (APA), directly after the fixed parameters on the stack, if any.

Function return values

The C compiler uses registers to store C function return values, depending on the function return types.

Return type	Return register
_Bool	r2
(unsigned) char	r2
(unsigned) short	r2
(unsigned) int	r2
(unsigned) long	r2r3
(unsigned) long long	r2r3r4
__int72_t	r2r3r4
__uint72_t	r2r3r4
float	r2r3
(long) double	r2r3r4
pointer to function / data / ARU / AEI / OREG / XOREG / WXREG	r2
struct / union* (size 24-bits)	r2
struct / union* (size 48-bits)	r2r3
struct / union* (size 72-bits)	r2r3r4

* Small struct/union types are returned through registers, except when any of the members has the `__aei_t` type.

Return values of an aggregate type that cannot be returned in registers or return values of the `__aei_t` type are returned in memory. When stack space is required, the caller allocates enough stack space to hold the return value and passes a pointer to the return value memory area to the called function in its first parameter register (r2). The called function stores the value to be returned at the memory location designated by the pointer in r2, and returns r2 again to the caller. The parameter allocation then continues as usual, with r2 being occupied. After the called function returns, the caller releases the stack space for the return value when necessary.

1.9.2. Register Usage

The C compiler uses the registers according to the convention given in the following table.

Register	Class	Purpose
r0	callee saves	local variables
r1	callee saves	local variables
r2 .. r3	caller saves	parameter passing and return values
r4	caller saves	parameter passing and return values and used for <code>mulu/muls</code> instructions and for the remainder result of <code>divu</code> and <code>divs</code> instructions
r5	caller saves	parameter passing and used for <code>mrdivo/mwrdivo</code> instructions
r6	callee saves	used for <code>jmpir/jbsir/jbcir/callir/ardir/awrir/nardir/wurmx/wurcx</code> instructions and local variables
r7	dedicated	stack pointer
rs0 .. rs3	caller saves	[optional, not EABI compliant] local variables
rs4 .. rs7	callee saves	[optional, not EABI compliant] local variables
mhb	scratch	intrinsic functions and the <code>__aei_t</code> type.
acb	scratch	intrinsic functions.

The registers are classified as follows:

- caller saves These registers are allowed to be changed by a function without saving the contents. Therefore, the calling function must save these registers when necessary prior to a function call.
- callee saves These registers belong to the calling function. These registers must be saved and restored by the called function, i.e. the caller expects them not to be changed after the function call.
- dedicated The dedicated registers have a specific purpose throughout the entire application and are always valid.
- scratch The scratch registers are never preserved.

1.9.3. Stack Usage

The stack is used for parameter passing and return values and for the allocation of automatic and temporary storage. The stack grows from lower addresses to higher addresses. The stack pointer (r7) points to the highest occupied word of the most recently allocated stack frame. The stack pointer alignment is 32-bit. The following figure outlines a stack frame.

The return address area is used to store the return address of a function call. The register save area is used to store the callee-saves registers when necessary. The local variables area is used to store local variables, function return values and spilled registers. The argument passing area is only used to pass stack parameters to the called functions. After control has been passed to the called function, this area is called the parameter area.

1.9.4. Variable Length Arrays

Variable length arrays (VLAs) are allocated on the heap using the `malloc()` and `free()` function calls from the C library.

1.9.5. Inlining Functions: inline

With the C compiler option `--optimize=+inline`, the C compiler automatically inlines small functions in order to reduce execution time (smart inlining). The compiler inserts the function body at the place the function is called. The C compiler decides which functions will be inlined. You can overrule this behavior with the two keywords `inline` (ISO-C) and `__noinline`.

With the `inline` keyword you force the compiler to inline the specified function, regardless of the optimization strategy of the compiler itself:

```
inline unsigned int abs(int val)
{
    unsigned int abs_val = val;
    if (val < 0) abs_val = -val;
}
```

```
    return abs_val;
}
```

If a function with the keyword `inline` is not called at all, the compiler does not generate code for it.

You must define inline functions in the same source module as in which you call the function, because the compiler only inlines a function in the module that contains the function definition. When you need to call the inline function from several source modules, you must include the definition of the inline function in each module (for example using a header file).

With the `__noinline` keyword, you prevent a function from being inlined:

```
__noinline unsigned int abs(int val)
{
    unsigned int abs_val = val;
    if (val < 0) abs_val = -val;
    return abs_val;
}
```

Using pragmas: `inline`, `noinline`, `smartinline`

Instead of the `inline` qualifier, you can also use `#pragma inline` and `#pragma noinline` to inline a function body:

```
#pragma inline
unsigned int abs(int val)
{
    unsigned int abs_val = val;
    if (val < 0) abs_val = -val;
    return abs_val;
}
#pragma noinline
void main( void )
{
    int i;
    i = abs(-1);
}
```

If a function has an `inline`/`__noinline` function qualifier, then this qualifier will overrule the current `pragma` setting.

With the `#pragma noinline`/`#pragma smartinline` you can temporarily disable the default behavior that the C compiler automatically inlines small functions when you turn on the [C compiler option `--optimize=+inline`](#).

With the [C compiler options `--inline-max-incr`](#) and [C compiler options `--inline-max-size`](#) you have more control over the automatic function inlining process of the compiler.

1.9.6. Channel Functions

To support the channels of an MCS, the TASKING C compiler for MCS supports an attribute and a function qualifier.

Defining a channel function: `channel()` attribute

With the function attribute `__attribute__((channel(channel)))` or with the function type qualifier `__channel(channel)` you can declare a function as a channel function.

```
void channel_x( void ) __attribute__((channel([channel])))
{
  ...
}
```

or:

```
void __channel([channel]) channel_x( void )
{
  ...
}
```

A function qualified with this attribute is called at program startup and serves as the entry point of the code executed by the specified channel. The argument *channel* is an integral number in the range 0..7 and is bound to the corresponding MCS channel. A channel can have only one entry point. For each channel function an unconditional jump to the function is inserted at the corresponding entry in the channel vector table (register MCS[i]_CH[x]_PC). Furthermore the stack pointer is initialized, unless the function does not use a stack. For example,

```
void channel_1( void ) __attribute__((channel(1)));

void channel_1( void ) /* inherit channel() attribute from prototype */
{
    return;
}
```

When the channel function returns the channel is disabled by clearing the EN flag in the STA register. A channel function does not save, nor restore any registers in its function prologue/epilogue.

The following rules apply:

- Only one channel function can be bound to a specific channel.
- Channel functions cannot return anything and must have a void argument type list.
- It is not possible to call a channel function directly from an application.

The C compiler will bind the channel function to the appropriate vector. For example:

```
        .global _vector_1
_vector_1 .equ    channel_1
```

Function `main()` is called from the startup code and is executed by channel 0 by default. However, you can execute `main()` from an arbitrary channel by specifying the macro `GTM_MCScore_MAIN_CHANNEL` to the linker for the specified MCS core. See [Section 5.7.3, Preprocessor Macros in the Linker Script Files](#) for more information. Function `main()` should not be qualified with the `channel()` attribute. If function `main()` returns then function `exit()` is called. The `exit()` function does not disable the channel but will loop forever.

Each function qualified with the `channel()` attribute initializes a private stack. The heap is shared between channels.

The `__csr` pointer qualifier

When you need to create a pointer to a channel function, it is advised to qualify the pointer with the `__csr` pointer qualifier. This prevents that a channel function is accidentally called directly from an application through a function pointer. When you omit the `__csr` pointer qualifier, the C compiler issues a warning. You can avoid this warning with an explicit type cast. The function attribute `__attribute__((channel(channel)))` automatically assigns the `__csr` pointer qualifier. When you use the `__csr` pointer qualifier without the `channel()` function attribute, the MCS C compiler binds the function to channel 0 by adding `__attribute__((channel(0)))`. Examples:

```
extern void chn( void ) __attribute__((channel(1)));
extern void f( void );

void      (*fp_a)( void );
void      (*fp_b)( void );
void      (*fp_c)( void );
void __csr (*fp_chn_a)( void );
void __csr (*fp_chn_b)( void );

int main( void )
{
    fp_a      = f;           /* ok, non-channel function, non-channel pointer */
    fp_chn_a = chn;         /* ok, channel function, channel pointer */
    fp_b      = chn;         /* warning, channel function, non-channel pointer */
    fp_chn_b = f;           /* ok, non-channel function, channel pointer */
    fp_c      = fp_chn_a;   /* warning, channel pointer assigned to
                             non-channel pointer */

    chn();                  /* error, cannot call a channel function */
    (*fp_chn_a)();         /* error, cannot call a channel function */
    return 0;
}
```

1.9.7. Intrinsic Functions

Some specific assembly instructions have no equivalence in C. *Intrinsic functions* give the possibility to use these instructions. Intrinsic functions are predefined functions that are recognized by the compiler. The compiler generates the most efficient assembly code for these functions.

The compiler always inlines the corresponding assembly instructions in the assembly source (rather than calling it as a function). This avoids parameter passing and register saving instructions which are normally necessary during function calls.

Intrinsic functions produce very efficient assembly code. Though it is possible to inline assembly code by hand, intrinsic functions use registers even more efficiently. At the same time your C source remains very readable.

You can use intrinsic functions in C as if they were ordinary C (library) functions. All intrinsics begin with a double underscore character (`__`).

Some intrinsic functions are available in two variants, with or without `__mcs__`, with similar semantics but different prototypes. You can choose which one fits best for your implementation.

1.9.7.1. Intrinsic Functions Used Internally by the C Compiler

Allocate a Variable Length Array

```
void * volatile __alloc( __size_t size );
```

Allocate memory. Returns a pointer to space of `size` bytes on the heap. Memory allocated through this function is freed when the calling function returns. This function is used internally for variable length arrays, it is not to be used by end users.

Free a Variable Length Array

```
void volatile __free( void * ptr );
```

Deallocate the memory pointed to by `ptr`. `ptr` must point to memory earlier allocated by a call to `__alloc()`.

Variable argument lists

```
char * __dotdotdot__( void );
```

Variable argument '...' operator. Used in library function `va_start()`. Returns a pointer to the start of the variable argument list on the stack.

1.9.7.2. ARU Transfer

Built-in type `__aru_t`

```
typedef struct {
    unsigned int  acb;
    unsigned int  data_l;
    unsigned int  data_h;
} __aru_t;
```

`__aru_t` is used by the intrinsic functions that provide access to the following MCS operations: ARD, AWR, ARDI, AWRI, NARD, NARDI, that update the registers: ACB, STA.CAT and STA.SAT.

Blocking ARU read access

```
__aru_t __ard( const __aru __aru_t * address, unsigned int * sta );
__aru_t __ard_l( const __aru __aru_t * address, unsigned int * sta );
__aru_t __ard_h( const __aru __aru_t * address, unsigned int * sta );
```

This function returns the two 24-bit values from the ARD[] instruction in the `data_h` and `data_l` fields of the return value, and the ARU control bits in the `acb` field of the return value. If the execution was not successful the return value is undefined.

The behavior of `__ard_l()` and `__ard_h()` is analogous to the behavior of `__ard()`, with the exception that the high 24-bit value is not transferred by `__ard_l()`, therefore the value in the `data_h` field of the return value is undefined. Similarly, for `__ard_h()` the value of `data_l` is undefined.

For example:

```
#include __SFRFILE__(tc39xb)

void test_ard( void )
{
    unsigned int sta;
    __aru_t      aru;

    aru = __ard( & TIM0_WRADDR(0), & sta );
}
```

This results in the following assembly:

```
addl  r7,#4
ard   r5,r4,#1
mwri  sta,r7
subl  r7,#4
```

Blocking ARU read access (`__mcs_variant`)

```
void __mcs_ard( unsigned int address, unsigned int * plword,
               unsigned int * phword);
```

Perform a blocking read access to the ARU, write the 24-bit high word received at the ARU port to the address specified by `phword` and write the 24-bit low word received at the ARU port to the address specified by `plword`. If one of these values is not required, the corresponding pointer may be NULL and the value is not written.

You can access the resulting ARU control bits afterwards with `__mcs_get_ACB()`, and you can access the resulting CAT and SAT flags of the register STA afterwards with `__mcs_get_STA()`. The transfer was successful if `SAT=1`. If the transfer failed, the data specified by `plword/phword` is undefined.

This function returns nothing.

Blocking ARU write access

```
unsigned int __awr( unsigned int index, __aru_t value );
```

Perform a blocking write access to the ARU and transfer two 24-bit values and the ARU control bits stored in `value` to the ARU port. The value of `index` must be $0 \leq \text{index} \leq 23$. If `index` is outside this range, the behavior is undefined.

This function generates the AWR instruction and returns the contents of the status register STA.

Blocking ARU write access (`__mcs_variant`)

```
void __mcs_awr( unsigned int index , unsigned int lword,
               unsigned int hword );
```

Perform a blocking write access to the ARU and transfer the `lword/hword` values to the ARU port. The value of `index` must be $0 \leq \text{index} \leq 23$. If `index` is outside this range, the behavior is undefined.

You can write to the ARU control bits with `__mcs_set_ACB()`. The CAT and SAT flags of the STA register are updated and you can access them afterwards with `__mcs_get_STA()`. The transfer was successful if `SAT=1`.

This function returns nothing.

Non-blocking ARU read access

```
__aru_t __nard( const __aru __aru_t * address, unsigned int * sta );
__aru_t __nard_l( const __aru __aru_t * address, unsigned int * sta );
__aru_t __nard_h( const __aru __aru_t * address, unsigned int * sta );
```

This function returns the two 24-bit values from the NARD[I] instruction in the `data_h` and `data_l` fields of the return value, and the ARU control bits in the `acb` field of the return value. If the execution was not successful the return value is undefined.

The behavior of `__nard_l()` and `__nard_h()` is analogous to the behavior of `__nard()`, with the exception that the high 24-bit value is not transferred by `__nard_l()`, therefore the value in the `data_h` field of the return value is undefined. Similarly, for `__nard_h()` the value of `data_l` is undefined.

For example:

```
#include __SFRFILE__(tc39xb)

void test_nard( void )
{
    unsigned int sta;
    __aru_t      aru;

    aru = __nard( &TIM0_WRADDR(0), &sta );
}
```

This results in the following assembly:

```
addl  r7,#4
nard  r5,r4,#1
mwri  sta,r7
subl  r7,#4
```

Non-blocking ARU read access (`__mcs_` variant)

```
void __mcs_nard( unsigned int address, unsigned int * plword,  
                unsigned int * phword);
```

Perform a non-blocking read access to the ARU, write the 24-bit high word received at the ARU port to the address specified by `phword` and write the 24-bit low word received at the ARU port to the address specified by `plword`. If one of these values is not required, the corresponding pointer may be NULL and the value is not written.

You can access the resulting ARU control bits afterwards with `__mcs_get_ACB()`, and you can access the resulting CAT and SAT flags of the register STA afterwards with `__mcs_get_STA()`. The transfer was successful if SAT=1. If the transfer failed, the data specified by `plword/phword` is undefined.

This function returns nothing.

1.9.7.3. Bus Master Addressing

Read access at bus master interface

```
__aei_t __brd( const volatile __aei __aei_t * address );
```

Initiate a read access at the bus master interface using the specified address.

This function generates the BRD instruction and returns the 32-bit value that is read from the bus master interface.

For example:

```
#include __SFRFILE__(tc39xb)  
  
unsigned int return_brd( void )  
{  
    return (unsigned int)__brd( & TIM_CH2_GPR0 );  
}
```

This results in the following assembly:

```
return_brd:    .type    func  
              brd      r2,256  
              ret
```

Read access at bus master interface (`__mcs_` variant)

```
__mcs_aei_t __mcs_brd( unsigned int address );
```

Initiate a read access at the bus master interface using the specified address.

This function generates the BRD instruction and returns the 32-bit value that is read from the bus master interface.

Write access at bus master interface

```
void __bwr( volatile __aei __aei_t * address, __aei_t value );
```

Initiate a write access at the bus master interface using the specified `address` and transfer a 32-bit value to the bus.

This function generates the BWR instruction and returns nothing.

For example:

```
#include __SFRFILE__(tc39xb)

void test_bwr( void )
{
    __bwr( & TIM_CH2_GPR0, 5 );
}
```

This results in the following assembly:

```
movl  r5,#5
movl  mhb,#0
bwr   r5,256
```

Write access at bus master interface (__mcs_ variant)

```
void __mcs_bwr( unsigned int address, __mcs_aei_t value );
```

Initiate a write access at the bus master interface using the specified `address` and transfer a 32-bit value to the bus.

This function generates the BWR instruction and returns nothing.

1.9.7.4. Suspending Wait Instructions**Wait until extended register match**

```
unsigned int __wurmx( volatile __wxreg unsigned int * sfr,
                    unsigned int value, unsigned int mask);
```

Suspend the current MCS channel until the value of the expression `sfr_value & mask == value` evaluates to `true`, where `sfr_value` is the current value of the SFR register identified by `sfr`. If `mask` is a compile-time constant that fits into 16 bits, only the lower 16 bits are used.

This function generates the WURMX or WURM instruction and returns the value of the status register STA.

For example:

```
__wurmx( & STRG, 0x8, 0x8 );
```

Wait until extended register match (`__mcs_` variant)

```
void __mcs_wurmx(unsigned int sfr, unsigned int value, unsigned int mask);
```

Suspend the current MCS channel until the value of the expression `sfr_value & mask == value` evaluates to `true`, where `sfr_value` is the current value of the SFR register identified by `sfr`.

`sfr` must be a compile-time constant, equal to the address offset of the corresponding SFR. `value` and `mask` can be constant or variables. If `mask` is a compile-time constant that fits into 16 bits, only the lower 16 bits are used.

This function changes the value of register STA, which you can read afterwards with `__mcs_get_STA()`. If the execution was successful `CWT=0`, otherwise the operation was canceled by the CPU.

This function returns nothing.

For example:

```
#define MCS_STRG (0x0b)

__mcs_wurmx( MCS_STRG, 0x8, 0x8 );
```

If you want to use the predefined SFR names, you need to cast the SFR to an `unsigned int` and use a pointer dereference:

```
#include __SFRFILE__(tc39xb) // include sfr/regtc39xb.sfr

__mcs_wurmx( (unsigned int) & STRG, 0x8, 0x8 );
```

Wait until extended register change

```
unsigned int __wurcx( volatile __wxreg unsigned int * sfr,
                    unsigned int value, unsigned int mask);
```

Suspend the current MCS channel until the value of the expression `sfr_value & mask != value` evaluates to `true`, where `sfr_value` is the current value of the SFR register identified by `sfr`. The lower 16 bits of `mask` are used.

This function generates the WURCX instruction and returns the value of the status register STA.

For example:

```
unsigned int a;

// wait until DPLL trigger status STA_T (bits 0 to 7 of DSTA) changes
a = DSTA & 0xF; // get actual state
__wurcx( & DSTA, a, 0xF ); // wait until state changes
```

Wait until extended register change (`__mcs_` variant)

```
void __mcs_wurcx( unsigned int sfr, unsigned int value, unsigned int mask);
```

Suspend the current MCS channel until the value of the expression `sfr_value & mask != value` evaluates to `true`, where `sfr_value` is the current value of the SFR register identified by `sfr`.

`sfr` must be a compile-time constant, equal to the address offset of the corresponding SFR. `value` and `mask` can be constant or variables.

This function changes the value of register `STA`, which you can read afterwards with `__mcs_get_STA()`. If the execution was successful `CWT=0`, otherwise the operation was canceled by the CPU.

This function returns nothing.

For example:

```
#define MCS_DSTA (0x1a)
unsigned int a;

// wait until DPLL trigger status STA_T (bits 0 to 7 of DSTA) changes
a = __mcs_get_DSTA() & 0xF; // get actual state
__mcs_wurcx( MCS_DSTA, a, 0xF ); // wait until state changes
```

Built-in type `__wuce_dir_t`

```
typedef enum
{
    __WUCE_FWD,
    __WUCE_BWD
} __wuce_dir_t;
```

The `__wuce_dir_t` type is used by the `__wuce()` intrinsic and specifies the counting direction.

Wait until cyclic event

```
unsigned int __wuce( volatile __oreg unsigned int * sfr,
                   unsigned int value, __wuce_dir_t direction );
```

Suspend the current MCS channel until a cyclic event compare matches.

The `sfr` argument must be one of the time base registers `TBU_TS0`, `TBU_TS1`, or `TBU_TS2`.

The `value` is the compare value and must not be larger than (forward) or smaller than (backward) half of the range of the total time base value (`0x7FFFFFFF`).

The `direction` specifies the counting direction of the time base register specified by `TBU_TSx`.

You can use the `__wuce()` intrinsic to synchronize an MCS program to a cyclic event generated by a TBU channel. If the event is in the future, the MCS channel suspends until the event occurs. If the event is in the past, the WUCE instruction is finished immediately.

This function generates the WUCE instruction and returns the value of the status register `STA`.

For example:

```
__wuce( & TBU_TS0, 0x187, __WUCE_FWD ); // wait until state changes
```

Wait until cyclic event (`__mcs_` variant)

```
void __mcs_wuce( unsigned int sfr, unsigned int value, _Bool direction );
```

Suspend the current MCS channel until a cyclic event compare matches.

The `sfr` argument must be one of the time base registers `TBU_TS0`, `TBU_TS1`, or `TBU_TS2` (equal to the address offset of the corresponding SFR).

The `value` is the compare value and must not be larger than (forward) or smaller than (backward) half of the range of the total time base value (`0x7FFFFFF`), otherwise the behavior is undefined.

The `direction` specifies the counting direction of the time base register specified by `TBU_TSx`: `direction=0` (false) assumes forward counting, `direction=1` (true) assumes backward counting.

You can use the `__mcs_wuce()` intrinsic to synchronize an MCS program to a cyclic event generated by a TBU channel. If the event is in the future, the MCS channel suspends until the event occurs. If the event is in the past, `__mcs_wuce()` execution finishes immediately.

This function changes the value of register `STA`, which you can read afterwards with `__mcs_get_STA()`. If the execution was successful `CWT=0`, otherwise the operation was canceled by the CPU.

This function returns nothing.

For example:

```
#define MCS_TBU_TS0 (0x0c) // read-only
#define MCS_TBU_TS1 (0x0d) // read-only
#define MCS_TBU_TS2 (0x0e) // read-only

// wait for TBU_TS0 value 0x187 (forward direction)
__mcs_wuce( MCS_TBU_TS0, 0x187, 0 ); // wait until state changes

// wait for TBU_TS1 value 0x17 (backward direction)
__mcs_wuce( MCS_TBU_TS1, 0x17, 1 ); // wait until state changes
```

1.9.7.5. SFR Direct Access

Several `__mcs_` variant intrinsics are available to access SFR registers. Note that you can also access SFR registers directly by means of defines, see [Section 1.2, *Special Function Registers*](#) for more information.

SFR get functions

```
unsigned int __mcs_get_STA(void);
unsigned int __mcs_get_ACB(void);
unsigned int __mcs_get_CTRG(void);
unsigned int __mcs_get_STRG(void);
unsigned int __mcs_get_MHB(void);
unsigned int __mcs_get_TBU_TS0(void);
unsigned int __mcs_get_TBU_TS1(void);
unsigned int __mcs_get_TBU_TS2(void);
```

```

unsigned int __mcs_get_GMI0(void);
unsigned int __mcs_get_GMI1(void);
unsigned int __mcs_get_DSTA(void);
unsigned int __mcs_get_DSTAX(void);

```

These functions return the current value of the corresponding SFR.

SFR set functions

```

void __mcs_set_STA(unsigned int data);
void __mcs_set_ACB(unsigned int data);
void __mcs_set_CTRG(unsigned int data);
void __mcs_set_STRG(unsigned int data);
void __mcs_set_MHB(unsigned int data);
void __mcs_set_GMI0(unsigned int data);
void __mcs_set_GMI1(unsigned int data);
void __mcs_set_DSTA(unsigned int data);
void __mcs_set_DSTAX(unsigned int data);

```

These functions write data into the corresponding SFR. TBU_TS0, TBU_TS1 and TBU_TS2 do not have set functions because those are read-only registers.

These functions return nothing.

1.9.7.6. Floating-Point

Extract sign bit from floating-point value

```

_Bool __signbit( double d );
_Bool __signbitf( float f );

```

Generate code to extract the sign bit from a floating-point value.

This function returns the sign bit of the floating-point argument.

Extract exponent from floating-point value

```

unsigned int __exp( double d );
unsigned int __expf( float f );

```

Generate code to extract the exponent from a floating-point value.

This function returns the exponent of the floating-point argument.

Extract mantissa from floating-point value

```

__uint72_t __mant( double d );
unsigned int __mantf( float f );

```

Generate code to extract the mantissa from a floating-point value.

This function returns the mantissa of the floating-point argument.

Extract exponent and mantissa from floating-point value

```
__uint72_t __expmant( double d );  
unsigned long __expmantf( float f );
```

Generate code to extract the exponent and mantissa from a floating-point value. The exponent is the most significant part of the returned value. Due to the special layout of float values on the MCS, the `__expmantf()` function leaves a gap of 1 bit between the exponent and the mantissa. In this bit the sign bit of the single precision floating-point value is stored. For double values the normal layout is used. The sign bit, either in the special or normal place, is always cleared.

This function returns the exponent and mantissa of the floating-point argument.

Construct floating-point value from sign, exponent and mantissa

```
double __pack( _Bool sign, unsigned int exp, __uint72_t mant );  
float __packf( _Bool sign, unsigned int exp, unsigned int mant );
```

Construct a floating-point value from the components sign, exponent and mantissa.

This function returns the constructed floating-point value.

Set exponent of floating-point value

```
double __set_exp( double d, unsigned int exp );  
float __set_expf( float f, unsigned int exp );
```

Set the exponent of a floating-point value. The biased representation is used, where the value 1 represents the minimum possible exponent value.

This function returns the updated floating-point value.

Set sign of floating-point value

```
double __set_sign( double d, _Bool sign );  
float __set_signf( float f, _Bool sign );
```

Set the sign of floating-point value.

This function returns the updated floating-point value.

Copy sign of floating-point value

```
double __copysign( double dst, double src );  
float __copysignf( float dst, float src );
```

Copy the sign of a source floating-point value to a destination floating-point value.

This function returns the updated floating-point value.

Create infinity value

```
double __inf( void );
float __inff( void );
```

Create a floating-point infinity value.

This function returns the floating-point infinity value.

Create NaN value

```
double __nan( void );
float __nanf( void );
```

Create a floating-point NaN value.

This function returns the floating-point NaN value.

1.9.7.7. Miscellaneous

Execute the NOP Instruction

```
void __nop( void );
```

or

```
void __mcs_nop( void );
```

Execute the NOP instruction.

This function returns nothing.

Disable current channel

```
void __halt( void );
```

Disable the current channel.

This function returns nothing.

1.10. Section Naming

By default the compiler generates section names that start with a dot ('.') and a section name prefix, extended with the module name and the name of the symbol that is allocated in the section. Each component is separated by a dot ('.'):

```
.prefix.module-name.symbol-name
```

You can rename sections with a pragma or with a command line option. The syntax is the same:

TASKING VX-toolset for MCS User Guide

```
--rename-sections=[[prefix=|all=][format_string]],...
```

```
#pragma section [[prefix=|all=][format_string]],...
```

With the *prefix* argument you select which sections are renamed. When the prefix of a section matches, the section name will get the specified *format_string* as suffix.

You can specify the following section name prefixes:

Section prefix	Description	Implicit section type
mcstext	program code	CODE
mcsdata	initialized data	DATA
mcsbss	uninitialized data (cleared)	DATA

When you omit the section prefix or use "**all**", all sections will be renamed.

With the *format_string* you specify the string that extends the ELF section name. The format string can contain characters and may contain the following format specifiers:

{ <i>attrib</i> }	Expands to the section attributes, separated by underscores. The cluster attribute, used when debug information is enabled, is not included.
{ <i>module</i> }	Expands to the basename of the module name.
{ <i>name</i> }	Expands to the object name, name of variable or function.

In format specifier expansions (for example, a module name with an extra dot), dots (".") are replaced by dollars ("\$").

When you omit the format string, a section will have a name that consist of a dot (".") and the section prefix only.

Note that `#pragma section mcstext=code,,mcsdata=special` will give all sections a name consisting of just the section prefix, except for `mcsdata` sections, which will be named `".mcsdata.special"`. The reason for this is that the double comma is interpreted as: **--rename-sections** or `#pragma section`, without arguments:

```
#pragma section mcstext=code,,mcsdata=special
```

is the same as:

```
#pragma section mcstext=code
#pragma section
#pragma section mcsdata=special
```

With `#pragma endsection` the naming convention of the previous level is restored, while with `#pragma section default` the default section naming convention is restored. Nesting of `pragma section/endsection` pairs will save the status of the previous level.

Example

The following example (file `test.c`) sets a default naming scheme for all sections, and then specializes the names for some sections.

```
#pragma section all=other.{name},mcsbss=region1.{name}
#pragma section mcstext=task1.{name}

int var1;          /* .mcsbss.region1.var1 */

#pragma section mcsbss={module}
                  /* assign module name to .mcsbss sections */

int var2;          /* .mcsbss.test      */

void f1( void )    /* .mcstext.task1.f1 */
{
    return;
}

void f2( void )    /* .mcstext.task1.f2 */
{
    return;
}

#pragma endsection /* pop last #pragma section from stack */

int var3;          /* .mcsbss.region1.var3 */
const int c = 3;   /* .mcsdata.other.c      */
int s1 = 5;        /* .mcsdata.other.s1     */
```

This example generates the following code:

```
.sdecl  '.mcstext.task1.f1'
.sect   '.mcstext.task1.f1'
.global f1
; Function f1
.align  4
f1:     .type   func
        ret
        ; End of function
        .size  f1,*-f1
        ; End of section

.sdecl  '.mcstext.task1.f2'
.sect   '.mcstext.task1.f2'
.global f2
; Function f2
.align  4
f2:     .type   func
```

TASKING VX-toolset for MCS User Guide

```
ret
; End of function
.size f2,*-f2
; End of section

.sdecl '.mcsbss.region1.var1'
.sect '.mcsbss.region1.var1'
.global var1
.align 4
.size var1, 4
var1: .type object
.space 1
; End of section

.sdecl '.mcsbss.test'
.sect '.mcsbss.test'
.global var2
.align 4
.size var2, 4
var2: .type object
.space 1
; End of section

.sdecl '.mcsbss.region1.var3'
.sect '.mcsbss.region1.var3'
.global var3
.align 4
.size var3, 4
var3: .type object
.space 1
; End of section

.sdecl '.mcsdata.other.c'
.sect '.mcsdata.other.c'
.global c
.align 4
.size c, 4
c: .type object
.word 3
; End of section

.sdecl '.mcsdata.other.s1'
.sect '.mcsdata.other.s1'
.global s1
.align 4
.size s1, 4
s1: .type object
.word 5
; End of section
```

Chapter 2. Assembly Language

This chapter describes the most important aspects of the TASKING assembly language for the Multi Channel Sequencer (MCS).

For a complete overview of the MCS v3.1 core, refer to the Generic Timer Module (GTM) chapter in the *AURIX TC3xx Target Specification* [V2.4.0, 2017-10, Infineon].

2.1. Assembly Syntax

An assembly program consists of statements. A statement may optionally be followed by a comment. Any source statement can be extended to more lines by including the line continuation character (\) as the last character on the line. The length of a source statement (first line and continuation lines) is only limited by the amount of available memory.

Mnemonics, directives and other keywords are case insensitive. Labels, symbols, directive arguments, and literal strings are case sensitive.

The syntax of an assembly statement is:

```
[label[:]] [instruction | directive | macro_call] [;comment]
```

label

A label is a special symbol which is assigned the value and type of the current program location counter. A label can consist of letters, digits and underscore characters (_). The first character cannot be a digit. The label can also be a *number*. A label which is prefixed by whitespace (spaces or tabs) has to be followed by a colon (:). The size of an identifier is only limited by the amount of available memory.

number is a number ranging from 1 to 255. This type of label is called a *numeric label* or *local label*. To refer to a numeric label, you must put an **n** (next) or **p** (previous) immediately after the label. This is required because the same label number may be used repeatedly.

Examples:

```
LAB1:      ; This label is followed by a colon and
           ; can be prefixed by whitespace
LAB1       ; This label has to start at the beginning
           ; of a line
1: jmp lp  ; This is an endless loop
           ; using numeric labels
```

<i>instruction</i>	<p>An instruction consists of a mnemonic and zero, one or more operands. It must not start in the first column.</p> <p>Operands are described in Section 2.3, Operands of an Assembly Instruction. The instructions are described in the Target Specification Manual.</p> <p>The instruction can also be a so-called 'generic instruction'. Generic instructions are pseudo instructions (no instructions from the instruction set). Depending on the situation in which a generic instruction is used, the assembler replaces the generic instruction with appropriate real assembly instruction(s). For a complete list, see Section 2.11, Generic Instructions.</p>
<i>directive</i>	<p>With directives you can control the assembler from within the assembly source. Except for preprocessing directives, these must not start in the first column. Directives are described in Section 2.9, Assembler Directives and Controls.</p>
<i>macro_call</i>	<p>A call to a previously defined macro. It must not start in the first column. See Section 2.10, Macro Operations.</p>
<i>comment</i>	<p>Comment, preceded by a ; (semicolon).</p>

You can use empty lines or lines with only comments.

Apart from the assembly statements as described above, you can put a so-called 'control line' in your assembly source file. These lines start with a \$ in the first column and alter the default behavior of the assembler.

\$control

For more information on controls see [Section 2.9, Assembler Directives and Controls](#).

2.2. Assembler Significant Characters

You can use all ASCII characters in the assembly source both in strings and in comments. Also the extended characters from the ISO 8859-1 (Latin-1) set are allowed.

Some characters have a special meaning to the assembler. Special characters associated with expression evaluation are described in [Section 2.6.3, Expression Operators](#). Other special assembler characters are:

Character	Description
;	Start of a comment
\	Line continuation character or macro operator: argument concatenation
?	Macro operator: return decimal value of a symbol
%	Macro operator: return hex value of a symbol
^	Macro operator: override local label
"	Macro string delimiter or quoted string .DEFINE expansion character
'	String constants delimiter

Character	Description
@	Start of a built-in assembly function
*	Location counter substitution
#	Constant number
++	String concatenation operator
[]	Substring delimiter

2.3. Operands of an Assembly Instruction

In an instruction, the mnemonic is followed by zero, one or more operands. An operand has one of the following types:

Operand	Description
<i>symbol</i>	A symbolic name as described in Section 2.4, Symbol Names . Symbols can also occur in expressions.
<i>register</i>	Any valid register name or register address as listed in Section 2.5, Registers .
<i>expression</i>	Any valid expression as described in Section 2.6, Assembly Expressions .
<i>address</i>	A combination of <i>expression</i> , <i>register</i> and <i>symbol</i> .

Addressing modes

The MCS assembly language has several addressing modes. These addressing modes are used for indirect memory addressing or indirect ARU addressing. For details see the Generic Timer Module (GTM) chapter in the *AURIX TC3xx Target Specification* [V2.4.0, 2017-10, Infineon].

2.4. Symbol Names

User-defined symbols

A user-defined *symbol* can consist of letters, digits, dots (.) and underscore characters (_). The first character cannot be a digit. The size of an identifier is only limited by the amount of available memory. The case of these characters is significant. You can define a symbol by means of a label declaration or an equate or set directive.

Predefined preprocessor symbols

These symbols start and end with two underscore characters, `__symbol__`, and you can use them in your assembly source to create conditional assembly. See [Section 2.4.1, Predefined Preprocessor Symbols](#).

Labels

Symbols used for memory locations are referred to as labels. It is allowed to use reserved symbols as labels as long as the label is followed by a colon.

Reserved symbols

Symbol names and other identifiers starting with a period (.) are reserved for the system (for example for directives or section names). Identifiers starting with an at sign ('@') are reserved for built-in assembler functions. Instructions are also reserved. The case of these built-in symbols is insignificant.

Examples

Valid symbol names:

```
loop_1
ENTRY
a_B_c
_aBC
```

Invalid symbol names:

```
1_loop      ; starts with a number
r1          ; reserved register name
.DEFINE     ; reserved directive name
```

2.4.1. Predefined Preprocessor Symbols

The TASKING assembler knows the predefined symbols as defined in the table below. The symbols are useful to create conditional assembly.

Symbol	Description
__ASMCS__	Identifies the assembler. You can use this symbol to flag parts of the source which must be recognized by the asmcs assembler only. It expands to 1.
__BUILD__	Identifies the build number of the assembler in the format yymmddqq (year, month, day and quarter in UTC).
__REVISION__	Expands to the revision number of the assembler. Digits are represented as they are; characters (for prototypes, alphas, betas) are represented by -1. Examples: v1.0r1 -> 1, v1.0rb -> -1
__TASKING__	Identifies the assembler as a TASKING assembler. Expands to 1 if a TASKING assembler is used.
__VERSION__	Identifies the version number of the assembler. For example, if you use version 2.1r1 of the assembler, __VERSION__ expands to 2001 (dot and revision number are omitted, minor version number in 3 digits).

Example

```
.if @defined('__ASMCS__')
    ; this part is only for the asmcs assembler
...
#endif
```

2.5. Registers

Register names

The following register names, either uppercase or lowercase, should not be used for user-defined symbol names in an assembly language source file:

```
R0 .. R7    (general purpose registers)
STA         (status register)
ACB         (ARU control bit register)
CTRG        (clear trigger bits register)
STRG        (set trigger bits register)
TBU_TS0     (TBU timestamp TS0 register)
TBU_TS1     (TBU timestamp TS1 register)
TBU_TS2     (TBU timestamp TS2 register)
MHB         (memory high byte register)
```

The extended register set is the same set of registers as above, plus:

```
RS0 .. RS7 (mirror of general purpose registers R0 .. R7)
DSTA        (DPLL status register)
DSTAX       (DPLL extended status register)
GMI0        (GTM Module Interrupt 0 register)
GMI1        (GTM Module Interrupt 1 register)
```

The extended register set is disabled by default. Note that the extended registers use the next MCS channel. You can enable the extended register set with [assembler option --extended-registers](#).

Register addresses

Instead of register names, the assembler also accepts register addresses in instructions. This is mainly for internal use by the compiler. It is not recommended to use this syntax in handwritten assembly, because it has a negative effect on the readability of the source.

For example, the following instruction:

```
mov sta, r1
```

Can also be written as:

```
mov 8, r1
mov sta, 1
mov 8, 1
```

All these instructions are identical. You can find the register addresses as "Address Offset" in the register descriptions in the *GTM-IP Generic Timer Module GTM-IP Specification* [Robert Bosch GmbH Automotive Electronics (AE)].

2.6. Assembly Expressions

An expression is a combination of symbols, constants, operators, and parentheses which represent a value that is used as an operand of an assembler instruction (or directive).

Expressions can contain user-defined labels (and their associated integer or floating-point values), and any combination of integers, floating-point numbers, or ASCII literal strings.

Expressions follow the conventional rules of algebra and boolean arithmetic.

Expressions that can be evaluated at assembly time are called *absolute expressions*. Expressions where the result is unknown until all sections have been combined and located, are called *relocatable* or *relative expressions*.

When any operand of an expression is relocatable, the entire expression is relocatable. Relocatable expressions are emitted in the object file and evaluated by the linker. Relocatable expressions can only contain integral functions; floating-point functions and numbers are not supported by the ELF/DWARF object format.

The assembler evaluates expressions with 64-bit precision in two's complement.

The syntax of an *expression* can be any of the following:

- *numeric constant*
- *string*
- *symbol*
- *expression binary_operator expression*
- *unary_operator expression*
- *(expression)*
- *function call*

All types of expressions are explained in separate sections.

2.6.1. Numeric Constants

Numeric constants can be used in expressions. If there is no prefix, by default the assembler assumes the number is a decimal number. Prefixes can be used in either lowercase or uppercase.

Base	Description	Example
Binary	A 0b or 0B prefix followed by binary digits (0,1).	0B1101 0b11001010
Hexadecimal	A 0x or 0X prefix followed by hexadecimal digits (0-9, A-F, a-f).	0X12FF 0x45 0xfa10

Base	Description	Example
Decimal integer	Decimal digits (0-9).	12 1245

2.6.2. Strings

ASCII characters, enclosed in single (') or double (") quotes constitute an ASCII string. Strings between double quotes allow symbol substitution by a `.DEFINE` directive, whereas strings between single quotes are always literal strings. Both types of strings can contain escape characters.

Strings constants in expressions are evaluated to a number (each character is replaced by its ASCII value). Strings in expressions can have a size of up to 4 characters or less depending on the operand of an instruction or directive; any subsequent characters in the string are ignored. In this case the assembler issues a warning. Null strings have a value of 0.

Square brackets (`[]`) delimit a substring operation in the form:

```
[string,offset,length]
```

offset is the start position within string. *length* is the length of the desired substring. Both values may not exceed the size of *string*.

Examples

```
'ABCD'           ; (0x41424344)
''79'           ; to enclose a quote double it
"A\"BC"         ; or to enclose a quote escape it
'AB'+1          ; (0x4143) string used in expression
''             ; null string
.word 'abcdef'  ; (0x64636261) 'ef' are ignored
                ; warning: string value truncated
'abc'++'de'     ; you can concatenate
                ; two strings with the '++' operator.
                ; This results in 'abcde'
['TASKING',0,4] ; results in the substring 'TASK'
```

2.6.3. Expression Operators

The next table shows the assembler operators. They are ordered according to their precedence. Operators of the same precedence are evaluated left to right. Parenthetical expressions have the highest priority (innermost first).

Valid operands include numeric constants, literal ASCII strings and symbols.

Most assembler operators can be used with both integer and floating-point values. If one operand has an integer value and the other operand has a floating-point value, the integer is converted to a floating-point value before the operator is applied. The result is a floating-point value.

Type	Operator	Name	Description
	()	parenthesis	Expressions enclosed by parenthesis are evaluated first.
Unary	+	plus	Returns the value of its operand.
	-	minus	Returns the negative of its operand.
	~	one's complement	Integer only. Returns the one's complement of its operand. It cannot be used with a floating-point operand.
	!	logical negate	Returns 1 if the operands' value is 0; otherwise 0. For example, if <code>buf</code> is 0 then <code>!buf</code> is 1. If <code>buf</code> has a value of 1000 then <code>!buf</code> is 0.
Arithmetic	*	multiplication	Yields the product of its operands.
	/	division	Yields the quotient of the division of the first operand by the second. For integer operands, the divide operation produces a truncated integer result.
	%	modulo	Integer only. This operator yields the remainder from the division of the first operand by the second.
	+	addition	Yields the sum of its operands.
	-	subtraction	Yields the difference of its operands.
Shift	<<	shift left	Integer only. Causes the left operand to be shifted to the left (and zero-filled) by the number of bits specified by the right operand.
	>>	shift right	Integer only. Causes the left operand to be shifted to the right by the number of bits specified by the right operand. The sign bit will be extended.
Relational	<	less than	Returns an integer 1 if the indicated condition is TRUE or an integer 0 if the indicated condition is FALSE.
	<=	less than or equal	
	>	greater than	
	>=	greater than or equal	For example, if <code>D</code> has a value of 3 and <code>E</code> has a value of 5, then the result of the expression <code>D<E</code> is 1, and the result of the expression <code>D>E</code> is 0.
	==	equal	
	!=	not equal	
Bit and Bitwise	&	AND	Integer only. Yields the bitwise AND function of its operand.
		OR	Integer only. Yields the bitwise OR function of its operand.
	^	exclusive OR	Integer only. Yields the bitwise exclusive OR function of its operands.

Type	Operator	Name	Description
Logical	&&	logical AND	Returns an integer 1 if both operands are non-zero; otherwise, it returns an integer 0.
		logical OR	Returns an integer 1 if either of the operands is non-zero; otherwise, it returns an integer 1

The relational operators and logical operators are intended primarily for use with the conditional assembly `.if` directive, but can be used in any expression.

2.7. Working with Sections

Sections are absolute or relocatable blocks of contiguous memory that can contain code or data. Some sections contain code or data that your program declared and uses directly, while other sections are created by the linker and contain debug information or code or data to initialize your application. These sections can be named in such a way that different modules can implement different parts of these sections. These sections are located in memory by the linker (using the linker script language, LSL) so that concerns about memory placement are postponed until after the assembly process.

All instructions and directives which generate data or code must be within an active section. The assembler emits a warning if code or data starts without a section definition and activation. If you program in assembly you have to define sections yourself.

For more information about locating sections see [Section 5.7.9, The Section Layout Definition: Locating Sections](#).

Section definition

Sections are defined with the `.SDECL` directive and have a name. A section may have attributes to instruct the linker to place it on a predefined starting address.

```
.SDECL "name"[, type][, attribute ]... [AT address]
```

The *name* specifies the name of the section. Section names that start with a dot '.' and a predefined section name prefix have a special meaning to the locating process. Optionally, you can extend the section names with a dot '.' and a user defined name. You can specify the following section name prefixes:

Section prefix	Description	Implicit section type
mcstext	program code	CODE
mcsdata	initialized data	DATA
mcsbss	uninitialized data (cleared)	DATA

See the description of the `.SDECL` [directive](#) for a complete description of all possible attributes.

Section activation

Sections are defined once and are activated with the `.SECT` directive.

TASKING VX-toolset for MCS User Guide

```
.SECT "name"
```

The linker will check between different modules and emits an error message if the section attributes do not match. The linker will also concatenate all matching section definitions into one section. So, all "code" sections will be linked into one big "code" chunk which will be located in one piece. A `.SECT` directive referring to an earlier defined section is called a *continuation*. Only the name can be specified.

Examples

```
.SDECL ".mcstext.code"  
.SECT ".mcstext.code"
```

Defines and activates a relocatable section in CODE memory. Other parts of this section, with the same name, may be defined in the same module or any other module. Other modules should use the same `.SDECL` statement. When necessary, it is possible to give the section an absolute starting address.

```
.SDECL ".mcsdata.abs", data at 0x100  
.SECT ".mcsdata.abs"
```

Defines and activates an absolute section named `.mcsdata.abs` starting at address 0x100.

2.8. Built-in Assembly Functions

The TASKING assembler has several built-in functions to support string comparison and macro testing. You can use functions as terms in any expression.

Syntax of an assembly function

```
@function_name([argument[,argument]...])
```

Functions start with the '@' character and have zero or more arguments, and are always followed by opening and closing parentheses. White space (a blank or tab) is not allowed between the function name and the opening parenthesis and between the (comma-separated) arguments.

The names of assembly functions are case insensitive.

Overview of mathematical functions

Function	Description
@POW(<i>expr1</i> , <i>expr2</i>)	Raise to a power
@SGN(<i>expr</i>)	Returns the sign of an expression as -1, 0 or 1

Overview of conversion functions

Function	Description
@CVI(<i>expr</i>)	Convert floating-point to integer
@RVB(<i>expr</i> [, <i>exprN</i>])	Reverse order of bits in field

Overview of string functions

Function	Description
@CAT (<i>str1</i> , <i>str2</i>)	Concatenate <i>str1</i> and <i>str2</i>
@LEN (<i>string</i>)	Length of string
@POS (<i>str1</i> , <i>str2</i> [, <i>start</i>])	Position of <i>str2</i> in <i>str1</i>
@SCP (<i>str1</i> , <i>str2</i>)	Compare <i>str1</i> with <i>str2</i>
@SUB (<i>str</i> , <i>expr1</i> , <i>expr2</i>)	Return substring

Overview of macro functions

Function	Description
@ARG (' <i>symbol</i> ' <i>expr</i>)	Test if macro argument is present
@CNT ()	Return number of macro arguments
@MAC (<i>symbol</i>)	Test if macro is defined
@MXP ()	Test if macro expansion is active

Overview of address calculation functions

Function	Description
@LSB (<i>expr</i>)	Least significant 8 bits of the expression
@MSB (<i>expr</i>)	Most significant 8 bits of the expression

Overview of assembler mode functions

Function	Description
@BIGENDIAN ()	Test if assembler generates code for big-endian mode
@DEF (' <i>symbol</i> ' <i>symbol</i>)	Returns 1 if symbol has been defined
@EXP (<i>expr</i>)	Expression check
@INT (<i>expr</i>)	Integer check
@LST ()	LIST control flag value

Detailed Description of Built-in Assembly Functions

@ARG('symbol' | expression)

Returns integer 1 if the macro argument represented by *symbol* or *expression* is present, 0 otherwise.

You can specify the argument with a *symbol* name (the name of a macro argument enclosed in single quotes) or with *expression* (the ordinal number of the argument in the macro formal argument list). If you use this function when macro expansion is not active, the assembler issues a warning.

TASKING VX-toolset for MCS User Guide

Example:

```
.IF @ARG('TWIDDLE') ;is argument twiddle present?  
.IF @ARG(1)          ;is first argument present?
```

@BIGENDIAN()

Returns 1 if the assembler generates code for big-endian mode, returns 0 if the assembler generates code for little-endian mode (this is the default).

@CAT(*string1*,*string2*)

Concatenates the two strings into one string. The two strings must be enclosed in single or double quotes.

Example:

```
.DEFINE ID "@CAT('TASK','ING')" ;ID = 'TASKING'
```

@CNT()

Returns the number of macro arguments of the current macro expansion as an integer. If you use this function when macro expansion is not active, the assembler issues a warning.

Example:

```
ARGCOUNT .SET @CNT() ; reserve argument count
```

@CVI(*expression*)

Converts the result of *expression* to an integer value. This function should be used with caution since the conversions can be inexact (e.g., floating-point values are truncated).

Example:

```
INT .SET @CVI(-1.05) ;INT = -1
```

@DEF(*'symbol' | symbol*)

Returns 1 if *symbol* has been defined, 0 otherwise. *symbol* can be any symbol or label not associated with a `.MACRO` or `.SDECL` directive. If *symbol* is quoted, it is looked up as a `.DEFINE` symbol; if it is not quoted, it is looked up as an ordinary symbol or label.

Example:

```
.IF @DEFINED('ANGLE') ;is symbol ANGLE defined?  
.IF @DEFINED(ANGLE)   ;does label ANGLE exist?
```

@EXP(*expression*)

Returns 0 if the evaluation of *expression* would normally result in an error. Returns 1 if the expression can be evaluated correctly. With the `@EXP` function, you prevent the assembler from generating an error

if the expression contains an error. No test is made by the assembler for warnings. The expression may be relative or absolute.

Example:

```
.IF  !@EXP(3/0)           ;Do the IF on error
                                ;assembler generates no error

.IF  !(3/0)               ;assembler generates an error
```

@INT(*expression*)

Returns integer 1 if *expression* has an integer result; otherwise, it returns a 0. The expression may be relative or absolute.

Example:

```
.IF  @INT(TERM)           ;Test if result is an integer
```

@LEN(*string*)

Returns the length of *string* as an integer.

Example:

```
SLEN  .SET  @LEN('string') ;SLEN = 6
```

@LSB(*expression*)

Returns the least significant 8 bits of the result of the *expression*. The result of the expression is calculated as 16 bit.

Example:

```
VAR1  .SET  @LSB(0x34)      ;VAR1 = 0x34
VAR2  .SET  @LSB(0x1234)   ;VAR2 = 0x34
VAR3  .SET  @LSB(0x654321) ;VAR3 = 0x21
```

@LST()

Returns the value of the \$LIST ON/OFF control flag as an integer. Whenever a \$LIST ON control is encountered in the assembler source, the flag is incremented; when a \$LIST OFF control is encountered, the flag is decremented.

Example:

```
.DUP  @ABS(@LST())        ;list unconditionally
```

@MAC(*symbol*)

Returns integer 1 if *symbol* has been defined as a macro name, 0 otherwise.

Example:

```
.IF @MAC(DOMUL) ;does macro DOMUL exist?
```

@MSB(*expression*)

Returns the most significant 8 bits of the result of the *expression*. The result of the expression is calculated as 16 bit.

Example:

```
VAR1 .SET @MSB(0x34) ;VAR1 = 0x00
VAR2 .SET @MSB(0x1234) ;VAR2 = 0x12
VAR3 .SET @MSB(0x654321) ;VAR3 = 0x43
```

@MXP()

Returns integer 1 if the assembler is expanding a macro, 0 otherwise.

Example:

```
.IF @MXP() ;macro expansion active?
```

@POS(*string1*,*string2*[,*start*])

Returns the position of *string2* in *string1* as an integer. If *string2* does not occur in *string1*, the last string position + 1 is returned.

With *start* you can specify the starting position of the search. If you do not specify *start*, the search is started from the beginning of *string1*. Note that the first position in a string is position 0.

Example:

```
ID1 .EQU @POS('TASKING','ASK') ; ID1 = 1
ID2 .EQU @POS('ABCDABCD','B',2) ; ID2 = 5
ID3 .EQU @POS('TASKING','BUG') ; ID3 = 7
```

@POW(*expression1*,*expression2*)

Returns *expression1* raised to the power *expression2* as a floating-point value. *expression1* and *expression2* must be separated by a comma.

Example:

```
BUF .EQU @CVI(@POW(2.0,3.0)) ;BUF = 8
```

@RVB(*expression1*,*expression2*)

Reverse the order of bits in *expression1* delimited by the number of bits in *expression2*. If *expression2* is omitted the field is bounded by the target word size. Both expressions must be 16-bit integer values.

Example:

```
VAR1 .SET @RVB(0x200) ;reverse all bits, VAR1=0x40
VAR2 .SET @RVB(0xB02) ;reverse all bits, VAR2=0x40D0
VAR3 .SET @RVB(0xB02,2) ;reverse bits 0 and 1,
;VAR3=0xB01
```

@SCP(*string1*,*string2*)

Returns integer 1 if the two strings compare, 0 otherwise. The two strings must be separated by a comma.

Example:

```
.IF @SCP(STR,'MAIN') ; does STR equal 'MAIN'?
```

@SGN(*expression*)

Returns the sign of *expression* as an integer: -1 if the argument is negative, 0 if zero, 1 if positive. The expression may be relative or absolute.

Example:

```
VAR1 .SET @SGN(-1.2e-92) ;VAR1 = -1
VAR2 .SET @SGN(0) ;VAR2 = 0
VAR3 .SET @SGN(28.382) ;VAR3 = 1
```

@SUB(*string*,*expression1*,*expression2*)

Returns the substring from *string* as a string. *expression1* is the starting position within *string*, and *expression2* is the length of the desired string. The assembler issues an error if either *expression1* or *expression2* exceeds the length of string. Note that the first position in a string is position 0.

Example:

```
.DEFINE ID "@SUB('TASKING',3,4)" ;ID = 'KING'
```

2.9. Assembler Directives and Controls

An assembler directive is simply a message to the assembler. Assembler directives are not translated into machine instructions. There are three main groups of assembler directives.

- Assembler directives that tell the assembler how to go about translating instructions into machine code. This is the most typical form of assembly directives. Typically they tell the assembler where to put a program in memory, what space to allocate for variables, and allow you to initialize memory with data. When the assembly source is assembled, a location counter in the assembler keeps track of where the code and data is to go in memory.

The following directives fall under this group:

- Assembly control directives

TASKING VX-toolset for MCS User Guide

- Symbol definition and section directives
- Data definition / Storage allocation directives
- High Level Language (HLL) directives
- Directives that are interpreted by the macro preprocessor. These directives tell the macro preprocessor how to manipulate your assembly code before it is actually being assembled. You can use these directives to write macros and to write conditional source code. Parts of the code that do not match the condition, will not be assembled at all.
- Some directives act as assembler options and most of them indeed do have an equivalent assembler (command line) option. The advantage of using a directive is that with such a directive you can overrule the assembler option for a particular part of the code. Directives of this kind are called *controls*. A typical example is to tell the assembler with an option to generate a list file while with the controls `$LIST ON` and `$LIST OFF` you overrule this option for a part of the code that you do not want to appear in the list file. Controls always appear on a separate line and start with a '\$' sign in the first column.

The following controls are available:

- Assembly listing controls
- Miscellaneous controls

Each assembler directive or control has its own syntax. You can use assembler directives and controls in the assembly code as pseudo instructions.

Some assembler directives can be preceded with a label. If you do not precede an assembler directive with a label, you must use white space instead (spaces or tabs). The assembler recognizes both uppercase and lowercase for directives.

2.9.1. Assembler Directives

Overview of assembly control directives

Directive	Description
<code>.COMMENT</code>	Start comment lines. You cannot use this directive in <code>.IF/.ELSE/.ENDIF</code> constructs and <code>.MACRO/.DUP</code> definitions.
<code>.END</code>	Indicates the end of an assembly module
<code>.FAIL</code>	Programmer generated error message
<code>.INCLUDE</code>	Include file
<code>.MESSAGE</code>	Programmer generated message
<code>.WARNING</code>	Programmer generated warning message

Overview of symbol definition and section directives

Directive	Description
<code>.ALIAS</code>	Create an alias for a symbol

Directive	Description
<code>.EQU</code>	Set permanent value to a symbol
<code>.EXTERN</code>	Import global section symbol
<code>.GLOBAL</code>	Declare global section symbol
<code>.LOCAL</code>	Declare local section symbol
<code>.ORG</code>	Initialize memory space and location counters to create a nameless section
<code>.SDECL</code>	Declare a section with name, type and attributes
<code>.SECT</code>	Activate a declared section
<code>.SET</code>	Set temporary value to a symbol
<code>.SIZE</code>	Set size of symbol in the ELF symbol table
<code>.TYPE</code>	Set symbol type in the ELF symbol table
<code>.WEAK</code>	Mark a symbol as 'weak'

Overview of data definition / storage allocation directives

Directive	Description
<code>.ALIGN</code>	Align location counter
<code>.SPACE</code>	Define storage (32 bits)
<code>.WORD</code>	Define word (32 bits)

Overview of macro preprocessor directives

Directive	Description
<code>.DEFINE</code>	Define substitution string
<code>.DUP, .ENDM</code>	Duplicate sequence of source lines
<code>.DUPA, .ENDM</code>	Duplicate sequence with arguments
<code>.DUPC, .ENDM</code>	Duplicate sequence with characters
<code>.DUPF, .ENDM</code>	Duplicate sequence in loop
<code>.IF, .ELIF, .ELSE</code>	Conditional assembly directive
<code>.ENDIF</code>	End of conditional assembly directive
<code>.EXITM</code>	Exit macro
<code>.MACRO, .ENDM</code>	Define macro
<code>.PMACRO</code>	Undefine (purge) macro
<code>.UNDEF</code>	Undefine <code>.DEFINE</code> symbol

Overview of HLL directives

Directive	Description
<code>.CALLS</code>	Pass call tree information and/or stack usage information

TASKING VX-toolset for MCS User Guide

Directive	Description
<code>.COMPILER_INVOCATION</code>	Pass C compiler invocation
<code>.COMPILER_NAME</code>	Pass C compiler name
<code>.COMPILER_VERSION</code>	Pass C compiler version header
<code>.MISRAC</code>	Pass MISRA C information

.ALIAS

Syntax

alias-name **.ALIAS** *symbol-name*

Description

With the `.ALIAS` directive you can create an alias of a symbol. The C compiler generates this directive when you use the `#pragma alias`.

Example

```
_exit .ALIAS _Exit
```

.ALIGN

Syntax

```
.ALIGN expression
```

Description

With the `.ALIGN` directive you instruct the assembler to align the location counter. By default the assembler aligns on four bytes.

When the assembler encounters the `.ALIGN` directive, it advances the location counter to an address that is aligned as specified by *expression* and places the next instruction or directive on that address. The alignment is in minimal addressable units (MAUs). The assembler fills the 'gap' with NOP instructions for code sections or with zeros for data sections. If the location counter is already aligned on the specified alignment, it remains unchanged. The location of absolute sections will not be changed.

The *expression* must be a power of two: 4, 8, 16, ... If you specify another value, the assembler changes the alignment to the next higher power of two and issues a warning.

The assembler aligns sections automatically to the largest alignment value occurring in that section.

A label is not allowed before this directive.

Example

```
.sdecl '.mcstext.code',code
.sect  '.mcstext.code'
.ALIGN 16      ; the assembler aligns
instruction ; this instruction at 16 MAUs and
                ; fills the 'gap' with NOP instructions.
```

```
.sdecl '.mcstext.code',code
.sect  '.mcstext.code'
.ALIGN 12      ; WRONG: not a power of two, the
instruction ; assembler aligns this instruction at
                ; 16 MAUs and issues a warning.
```

.CALLS

Syntax

```
.CALLS 'caller', 'callee'
```

or

```
.CALLS 'caller', '', stack_usage
```

Description

The first syntax creates a call graph reference between *caller* and *callee*. The linker needs this information to build a call graph. *caller* and *callee* are names of functions.

The second syntax specifies stack information. When *callee* is an empty name, this means we define the stack usage of the function itself. The value specified is the stack usage in bytes at the time of the call including the return address.

This information is used by the linker to compute the used stack within the application. The information is found in the generated linker map file within the Memory Usage.

This directive is generated by the C compiler. Normally you will not use it in hand-coded assembly.

A label is not allowed before this directive.

Example

```
.CALLS 'main', 'nfunc'
```

Indicates that the function `main` calls the function `nfunc`.

```
.CALLS 'main', '', 8
```

The function `main` uses 8 bytes on the stack.

.COMMENT

Syntax

```
.COMMENT delimiter  
.  
.  
delimiter
```

Description

With the `.COMMENT` directive you can define one or more lines as comments. The first non-blank character after the `.COMMENT` directive is the comment delimiter. The two delimiters are used to define the comment text. The line containing the second comment delimiter will be considered the last line of the comment. The comment text can include any printable characters and the comment text will be produced in the source listing as it appears in the source file.

A label is not allowed before this directive.

Example

```
.COMMENT + This is a one line comment +  
.COMMENT * This is a multiple line  
           comment. Any number of lines  
           can be placed between the two  
           delimiters.  
           *
```

.COMPILER_INVOCATION, .COMPILER_NAME, .COMPILER_VERSION

Syntax

```
.COMPILER_VERSION "version_header"  
.COMPILER_INVOCATION "invocation"  
.COMPILER_NAME "name"
```

Description

The C compiler generates information about itself and the invocation at the start of the assembly source. This way you can always see how the assembly source file was generated. When you assemble the source file, this information will appear in `.note` sections in the object file.

A label is not allowed before these directives.

Example

```
.COMPILER_VERSION "TASKING VX-toolset for MCS: C compiler vx.yrz Build yymddqg"  
.COMPILER_INVOCATION "cmcs test.c"  
.COMPILER_NAME "cmcs"
```

.DEFINE

Syntax

```
.DEFINE symbol string
```

Description

With the `.DEFINE` directive you define a substitution string that you can use on all following source lines. The assembler searches all succeeding lines for an occurrence of *symbol*, and replaces it with *string*. If the *symbol* occurs in a double quoted string it is also replaced. Strings between single quotes are not expanded.

This directive is useful for providing better documentation in the source program. A *symbol* can consist of letters, digits and underscore characters (`_`), and the first character cannot be a digit.

Macros represent a special case. `.DEFINE` directive translations will be applied to the macro definition as it is encountered. When the macro is expanded, any active `.DEFINE` directive translations will again be applied.

The assembler issues a warning if you redefine an existing symbol.

A label is not allowed before this directive.

Example

Suppose you defined the symbol `LEN` with the substitution string "32":

```
.DEFINE LEN "32"
```

Then you can use the symbol `LEN` for example as follows:

```
.SPACE LEN  
.MESSAGE "The length is: LEN"
```

The assembler preprocessor replaces `LEN` with "32" and assembles the following lines:

```
.SPACE 32  
.MESSAGE "The length is: 32"
```

Related Information

`.UNDEF` (Undefine a `.DEFINE` symbol)

`.MACRO`, `.ENDM` (Define a macro)

.DUP, .ENDM

Syntax

```
[label:] .DUP expression
      . . . .
      .ENDM
```

Description

With the `.DUP/.ENDM` directive you can duplicate a sequence of assembly source lines. With *expression* you specify the number of duplications. If the *expression* evaluates to a number less than or equal to 0, the sequence of lines will not be included in the assembler output. The *expression* result must be an absolute integer and cannot contain any forward references (symbols that have not already been defined). The `.DUP` directive may be nested to any level.

If you specify *label*, it gets the value of the location counter at the start of the directive processing.

Example

In this example the loop is repeated three times. Effectively, the preprocessor repeats the source lines (`.WORD 10`) three times, then the assembler assembles the result:

```
.DUP 3
.WORD 10 ; assembly source lines
.ENDM
```

Related Information

- [.DUPA, .ENDM](#) (Duplicate sequence with arguments)
- [.DUPC, .ENDM](#) (Duplicate sequence with characters)
- [.DUPF, .ENDM](#) (Duplicate sequence in loop)
- [.MACRO, .ENDM](#) (Define a macro)

.DUPA, .ENDM

Syntax

```
[label:] .DUPA formal_arg,argument[,argument]...  
    ....  
    .ENDM
```

Description

With the `.DUPA/.ENDM` directive you can repeat a block of source statements for each *argument*. For each repetition, every occurrence of the *formal_arg* parameter within the block is replaced with each succeeding *argument* string. If an argument includes an embedded blank or other assembler-significant character, it must be enclosed with single quotes.

If you specify *label*, it gets the value of the location counter at the start of the directive processing.

Example

Consider the following source input statements,

```
.DUPA VALUE,12,,32,34  
.WORD VALUE  
.ENDM
```

This is expanded as follows:

```
.WORD 12  
.WORD VALUE ; results in a warning  
.WORD 32  
.WORD 34
```

The second statement results in a warning of the assembler that the local symbol `VALUE` is not defined in this module and is made external.

Related Information

- `.DUP`, `.ENDM` (Duplicate sequence of source lines)
- `.DUPC`, `.ENDM` (Duplicate sequence with characters)
- `.DUPF`, `.ENDM` (Duplicate sequence in loop)
- `.MACRO`, `.ENDM` (Define a macro)

.DUPC, .ENDM

Syntax

```
[label:] .DUPC formal_arg,string
        ....
        .ENDM
```

Description

With the `.DUPC/.ENDM` directive you can repeat a block of source statements for each character within *string*. For each character in the string, the *formal_arg* parameter within the block is replaced with that character. If the string is empty, then the block is skipped.

If you specify *label*, it gets the value of the location counter at the start of the directive processing.

Example

Consider the following source input statements,

```
.DUPC  VALUE, '123'
.WORD  VALUE
.ENDM
```

This is expanded as follows:

```
.WORD  1
.WORD  2
.WORD  3
```

Related Information

- `.DUP`, `.ENDM` (Duplicate sequence of source lines)
- `.DUPA`, `.ENDM` (Duplicate sequence with arguments)
- `.DUPF`, `.ENDM` (Duplicate sequence in loop)
- `.MACRO`, `.ENDM` (Define a macro)

.DUPF, .ENDM

Syntax

```
[label:] .DUPF formal_arg,[start],end[,increment]  
    . . .  
    .ENDM
```

Description

With the `.DUPF/.ENDM` directive you can repeat a block of source statements $(end - start) + 1 / increment$ times. *start* is the starting value for the loop index; *end* represents the final value. *increment* is the increment for the loop index; it defaults to 1 if omitted (as does the *start* value). The *formal_arg* parameter holds the loop index value and may be used within the body of instructions.

If you specify *label*, it gets the value of the location counter at the start of the directive processing.

Example

Consider the following source input statements,

```
.DUPF  NUM, 0, 7  
.WORD  NUM  
.ENDM
```

This is expanded as follows:

```
.WORD  0  
.WORD  1  
.WORD  2  
.WORD  3  
.WORD  4  
.WORD  5  
.WORD  6  
.WORD  7
```

Related Information

- `.DUP` , `.ENDM` (Duplicate sequence of source lines)
- `.DUPA` , `.ENDM` (Duplicate sequence with arguments)
- `.DUPC` , `.ENDM` (Duplicate sequence with characters)
- `.MACRO` , `.ENDM` (Define a macro)

.END

Syntax

.END

Description

With the optional `.END` directive you tell the assembler that the end of the module is reached. If the assembler finds assembly source lines beyond the `.END` directive, it ignores those lines and issues a warning.

You cannot use the `.END` directive in a macro expansion.

The assembler does not allow a label with this directive.

Example

```
        ; source lines  
.END          ; End of assembly module
```

Related Information

-

.EQU

Syntax

symbol **.EQU** *expression*

Description

With the `.EQU` directive you assign the value of *expression* to *symbol* permanently. The expression can be relocatable or absolute and forward references are allowed. Once defined, you cannot redefine the symbol. With the `.GLOBAL` directive you can declare the symbol global.

Example

To assign the value 0x400 permanently to the symbol `MYSYMBOL`:

```
MYSYMBOL .EQU 0x4000
```

You cannot redefine the symbol `MYSYMBOL` after this.

Related Information

`.SET` (Set temporary value to a symbol)

.EXITM

Syntax

```
.EXITM
```

Description

With the `.EXITM` directive the assembler will immediately terminate a macro expansion. It is useful when you use it with the conditional assembly directive `.IF` to terminate macro expansion when, for example, error conditions are detected.

A label is not allowed before this directive.

Example

```
CALC  .MACRO  XVAL,YVAL
      .IF    XVAL<0
      .FAIL  'Macro parameter value out of range'
      .EXITM ;Exit macro
      .ENDIF
      .
      .
      .
      .ENDM
```

Related Information

- `.DUP` , `.ENDM` (Duplicate sequence of source lines)
- `.DUPA` , `.ENDM` (Duplicate sequence with arguments)
- `.DUPC` , `.ENDM` (Duplicate sequence with characters)
- `.DUPF` , `.ENDM` (Duplicate sequence in loop)
- `.MACRO` , `.ENDM` (Define a macro)

.EXTERN

Syntax

```
.EXTERN symbol[,symbol]...
```

Description

With the `.EXTERN` directive you define an *external* symbol. It means that the specified symbol is referenced in the current module, but is not defined within the current module. This symbol must either have been defined outside of any module or declared as globally accessible within another module with the `.GLOBAL` directive.

If you do not use the `.EXTERN` directive and the symbol is not defined within the current module, the assembler issues a warning and inserts the `.EXTERN` directive.

A label is not allowed with this directive.

Example

```
.EXTERN AA,CC,DD      ;defined elsewhere
.sdecl ".mcstext"
.sect ".mcstext"
.
.
movl R3,AA      ; AA is used here
.
```

Related Information

[.GLOBAL](#) (Declare global section symbol)

[.LOCAL](#) (Declare local section symbol)

.FAIL

Syntax

```
.FAIL {str|exp}[,{str|exp}]...
```

Description

With the `.FAIL` directive you tell the assembler to print an error message to `stderr` during the assembling process.

An arbitrary number of strings and expressions, in any order but separated by commas with no intervening white space, can be specified to describe the nature of the generated error. If you use expressions, the assembler outputs the result. The assembler outputs a space between each argument.

The total error count will be incremented as with any other error. The `.FAIL` directive is for example useful in combination with conditional assembly for exceptional condition checking. The assembly process proceeds normally after the error has been printed.

With this directive the assembler exits with exit code 1 (an error).

A label is not allowed with this directive.

Example

```
.FAIL 'Parameter out of range'
```

This results in the error:

```
E143: ["filename" line] Parameter out of range
```

Related Information

[.MESSAGE](#) (Programmer generated message)

[.WARNING](#) (Programmer generated warning)

.GLOBAL

Syntax

```
.GLOBAL symbol [, symbol] . . .
```

Description

All symbols or labels defined in the current section or module are local to the module by default. You can change this default behavior with [assembler option --symbol-scope=global](#).

With the `.GLOBAL` directive you declare one or more symbols as global. It means that the specified symbols are defined within the current section or module, and that those definitions should be accessible by all modules.

To access a symbol, defined with `.GLOBAL`, from another module, use the `.EXTERN` directive.

Only program labels and symbols defined with `.EQU` can be made global.

If the symbols that appear in the operand field are not used in the module, the assembler gives a warning.

The assembler does not allow a label with this directive.

Example

```
.sdecl  '.mcsdata.data'
.sect   '.mcsdata.data'
.GLOBAL LOOPA ; LOOPA will be globally
                ; accessible by other modules
LOOPA .EQU 1    ; definition of symbol LOOPA
```

Related Information

[.EXTERN](#) (Import global section symbol)

[.LOCAL](#) (Declare local section symbol)

.IF, .ELIF, .ELSE, .ENDIF

Syntax

```
.IF expression
.
.
[.ELIF expression] ; the .ELIF directive is optional
.
.
[.ELSE] ; the .ELSE directive is optional
.
.
.ENDIF
```

Description

With the **.IF/.ENDIF** directives you can create a part of conditional assembly code. The assembler assembles only the code that matches a specified condition.

The *expression* must evaluate to an absolute integer and cannot contain forward references. If *expression* evaluates to zero, the IF-condition is considered FALSE, any non-zero result of *expression* is considered as TRUE.

If the optional **.ELSE** and/or **.ELIF** directives are not present, then the source statements following the **.IF** directive and up to the next **.ENDIF** directive will be included as part of the source file being assembled only if the *expression* had a non-zero result.

If the *expression* has a value of zero, the source file will be assembled as if those statements between the **.IF** and the **.ENDIF** directives were never encountered.

If the **.ELSE** directive is present and *expression* has a nonzero result, then the statements between the **.IF** and **.ELSE** directives will be assembled, and the statement between the **.ELSE** and **.ENDIF** directives will be skipped. Alternatively, if *expression* has a value of zero, then the statements between the **.IF** and **.ELSE** directives will be skipped, and the statements between the **.ELSE** and **.ENDIF** directives will be assembled.

You can nest **.IF** directives to any level. The **.ELSE** and **.ELIF** directive always refer to the nearest previous **.IF** directive.

A label is not allowed with this directive.

Example

Suppose you have an assemble source file with specific code for a test version, for a demo version and for the final version. Within the assembly source you define this code conditionally as follows:

```
.IF TEST
... ; code for the test version
.ELIF DEMO
... ; code for the demo version
.ELSE
```

```
... ; code for the final version  
.ENDIF
```

Before assembling the file you can set the values of the symbols `TEST` and `DEMO` in the assembly source before the `.IF` directive is reached. For example, to assemble the demo version:

```
TEST .SET 0  
DEMO .SET 1
```

You can also define the symbols on the command line with the [assembler option --define \(-D\)](#):

```
asmcs --define=DEMO --define=TEST=0 test.asm
```

.INCLUDE

Syntax

```
.INCLUDE "filename" | <filename>
```

Description

With the `.INCLUDE` directive you include another file at the exact location where the `.INCLUDE` occurs. This happens before the resulting file is assembled. The `.INCLUDE` directive works similarly to the `#include` statement in C. The source from the include file is assembled as if it followed the point of the `.INCLUDE` directive. When the end of the included file is reached, assembly of the original file continues.

The string specifies the filename of the file to be included. The filename must be compatible with the operating system (forward/backward slashes) and can contain a directory specification.

If an absolute pathname is specified, the assembler searches for that file. If a relative path is specified or just a filename, the order in which the assembler searches for include files is:

1. The current directory if you use the "filename" construction.
The current directory is not searched if you use the <filename> syntax.
2. The path that is specified with the [assembler option --include-directory](#).
3. The path that is specified in the environment variable `ASMCSINC` when the product was installed.
4. The default `include` directory in the installation directory.

The assembler does not allow a label with this directive.

Example

```
.INCLUDE 'storage\mem.asm'    ; include file  
.INCLUDE <data.asm>         ; Do not look in  
                             ; current directory
```

.LOCAL

Syntax

```
.LOCAL symbol[,symbol]. . .
```

Description

All symbols or labels defined in the current section or module are local to the module by default. You can change this default behavior with [assembler option --symbol-scope=global](#).

With the `.LOCAL` directive you declare one or more symbols as local. It means that the specified symbols are explicitly local to the module in which you define them.

If the symbols that appear in the operand field are not used in the module, the assembler gives a warning.

The assembler does not allow a label with this directive.

Example

```
.SDECL ".mcsdata.data",DATA
.SECT ".mcsdata.data"
.LOCAL LOOPA ; LOOPA is local to this section

LOOPA .WORD 0x100 ; assigns the value 0x100 to LOOPA
```

Related Information

[.EXTERN](#) (Import global section symbol)

[.GLOBAL](#) (Declare global section symbol)

.MACRO, .ENDM

Syntax

```
macro_name .MACRO [argument[,argument]...]
...
macro_definition_statements
...
.ENDM
```

Description

With the `.MACRO` directive you define a macro. Macros provide a shorthand method for handling a repeated pattern of code or group of instructions. You can define the pattern as a macro, and then call the macro at the points in the program where the pattern would repeat.

The definition of a macro consists of three parts:

- *Header*, which assigns a name to the macro and defines the arguments (`.MACRO` directive).
- *Body*, which contains the code or instructions to be inserted when the macro is called.
- *Terminator*, which indicates the end of the macro definition (`.ENDM` directive).

The arguments are symbolic names that the macro processor replaces with the literal arguments when the macro is expanded (called). Each formal *argument* must follow the same rules as symbol names: the name can consist of letters, digits and underscore characters (`_`). The first character cannot be a digit. Argument names cannot start with a percent sign (`%`).

Macro definitions can be nested but the nested macro will not be defined until the primary macro is expanded.

You can use the following operators in macro definition statements:

Operator	Name	Description
<code>\</code>	Macro argument concatenation	Concatenates a macro argument with adjacent alphanumeric characters.
<code>?</code>	Return decimal value of symbol	Substitutes the <code>?symbol</code> sequence with a character string that represents the decimal value of the symbol.
<code>%</code>	Return hex value of symbol	Substitutes the <code>%symbol</code> sequence with a character string that represents the hexadecimal value of the symbol.
<code>"</code>	Macro string delimiter	Allows the use of macro arguments as literal strings.
<code>^</code>	Macro local label override	Prevents name mangling on labels in macros.

Example

The macro definition:

```
CONST24 .MACRO  reg,value           ;header
        movl   reg,value           ;body
        .ENDM                       ;terminator
```

The macro call:

```
.SDECL  ".mcstext.code",code
.SECT   ".mcstext.code"
CONST24 r5,0x123456
```

The macro expands as follows:

```
movl    r5,0x123456
```

- [.DEFINE](#) (Define a substitution string)

.MESSAGE

Syntax

```
.MESSAGE {str|exp}[,{str|exp}]...
```

Description

With the `.MESSAGE` directive you tell the assembler to print a message to `stderr` during the assembling process.

An arbitrary number of strings and expressions, in any order but separated by commas with no intervening white space, can be specified to describe the nature of the generated message. If you use expressions, the assembler outputs the result. The assembler outputs a space between each argument.

The error and warning counts will not be affected. The `.MESSAGE` directive is for example useful in combination with conditional assembly to indicate which part is assembled. The assembling process proceeds normally after the message has been printed.

This directive has no effect on the exit code of the assembler.

A label is not allowed with this directive.

Example

```
.DEFINE LONG "SHORT"  
.MESSAGE 'This is a LONG string'  
.MESSAGE "This is a LONG string"
```

Within single quotes, the defined symbol `LONG` is not expanded. Within double quotes the symbol `LONG` is expanded so the actual message is printed as:

```
This is a LONG string  
This is a SHORT string
```

Related Information

[.FAIL](#) (Programmer generated error)

[.WARNING](#) (Programmer generated warning)

.MISRAC

Syntax

```
.MISRAC string
```

Description

The C compiler can generate the `.MISRAC` directive to pass the compiler's MISRA C settings to the object file. The linker performs checks on these settings and can generate a report. It is not recommended to use this directive in hand-coded assembly.

Example

```
.MISRAC 'MISRA-C:2004,64,e2,0b,e,e11,27,6,ef83,e1,  
ef,66,cb75,afl,eff,e7,e7f,8d,63,87ff7,6ff3,4'
```

Related Information

Section 3.6.2, *C Code Checking: MISRA C*

C compiler option **--misrac**

.ORG

Syntax

```
.ORG [abs-loc][,sect_type][,attribute]. . .
```

Description

With the `.ORG` directive you can specify an absolute location (*abs_loc*) in memory of a section. This is the same as a `.SDECL/ .SECT` without a section name.

This directive uses the following arguments:

<i>abs-loc</i>	Initial value to assign to the run-time location counter. <i>abs-loc</i> must be an absolute expression. If <i>abs_loc</i> is not specified, then the value is zero.
<i>sect_type</i>	An optional section type: code or data
<i>attribute</i>	An optional section attribute: init, noread, noclear, max, rom, group(<i>string</i>), cluster(<i>string</i>), protect

For more information about the section types and attributes see the [assembler directive .SDECL](#).

The section type and attributes are case insensitive. A label is not allowed with this directive.

Example

```
; define a section at location 100 decimal
.org 100

; define a relocatable nameless section
.org

; define a relocatable data section
.org ,data

; define a data section at 0x8000
.org 0x8000,data
```

Related Information

[.SDECL](#) (Declare section name and attributes)

[.SECT](#) (Activate a declared section)

.PMACRO

Syntax

```
.PMACRO symbol[,symbol]. . .
```

Description

With the `.PMACRO` directive you tell the assembler to undefine the specified macro, so that later uses of the symbol will not be expanded.

The assembler does not allow a label with this directive.

Example

```
.PMACRO MAC1,MAC2
```

This statement causes the macros named `MAC1` and `MAC2` to be undefined.

Related Information

`.MACRO`, `.ENDM` (Define a macro)

.SDECL

Syntax

```
.SDECL "name" [, type] [, attribute]... [AT address]
```

Description

With the `.SDECL` directive you can define a section with a *name* (between single or double quotes), *type* and optional *attributes*. Before any code or data can be placed in a section, you must use the `.SECT` directive to activate the section.

The *name* specifies the name of the section. Section names that start with a dot '.' and a predefined section name prefix have a special meaning to the locating process. Optionally, you can extend the section names with a dot '.' and a user defined name. You can specify the following section name prefixes:

Section prefix	Description	Implicit section type
mcstext	program code	CODE
mcsdata	initialized data	DATA
mcsbss	uninitialized data (cleared)	DATA

The *type* operand specifies the section's type and must be one of:

Type	Description
CODE	Code section.
DATA	Data section.
DEBUG	Debug section.

When you use a section prefix, the section type is optional.

The section type and attributes are case insensitive.

The defined *attributes* are:

Attribute	Description	Allowed on type
AT <i>address</i>	Locate the section at the given <i>address</i> .	CODE, DATA
CLEAR	Sections are zeroed at startup.	DATA
CLUSTER(' <i>name</i> ')	Cluster code sections with companion debug sections. Used by the linker during removal of unreferenced sections. The name must be unique for this module (not for the application). To prevent naming conflicts with other symbols, the prefix ".cluster." is added to the cluster name during object file generation.	CODE, DATA, DEBUG
CONCAT	Concatenate sections. Used by the linker to merge sections with the same name.	DATA

Attribute	Description	Allowed on type
INIT	Defines that the section contains initialization data, which is copied from ROM to RAM at program startup.	CODE, DATA
NOCLEAR	Sections are not zeroed at startup. This is a default attribute for data sections. This attribute is only useful with BSS sections, which are cleared at startup by default.	DATA
NOREAD	Defines that the section can be executed from but not read.	CODE
PROTECT	Tells the linker to exclude a section from unreferenced section removal and duplicate section removal.	CODE, DATA
ROM	Section contains data to be placed in ROM. This ROM area is not executable.	CODE, DATA

Section names

The *name* of a section can have a special meaning for locating sections. The name of code sections should always start with ".mcstext". The name of data sections should always start with ".mcsdata".

Example

```
.sdecl ".mcstext.mycode"           ; declare mcscode section
.sect  ".mcstext.mycode"           ; activate section

.sdecl ".mcsdata.mydata"           ; declare mcsdata section
.sect  ".mcsdata.mydata"           ; activate section

.sdecl ".mcsdata.abssec", data at 0x100
                                           ; absolute section
.sect  ".mcsdata.abssec"           ; activate section
```

Related Information

[.SECT](#) (Activate a declared section)

.SECT

Syntax

```
.SECT "name"
```

Description

With the `.SECT` directive you activate a previously declared section with the name *name*. Before you can activate a section, you must define the section with the `.SDECL` directive. You can activate a section as many times as you need.

Example

```
.sdecl ".mcsdata.mydata" ; declare mcsdata section  
.sect ".mcsdata.mydata" ; activate section
```

Related Information

[.SDECL](#) (Declare section name and attributes)

.SET

Syntax

```
symbol .SET expression  
  
      .SET symbol expression
```

Description

With the `.SET` directive you assign the value of *expression* to symbol *temporarily*. If a symbol was defined with the `.SET` directive, you can redefine that symbol in another part of the assembly source, using the `.SET` directive again. Symbols that you define with the `.SET` directive are always local: you cannot define the symbol global with the `.GLOBAL` directive.

The `.SET` directive is useful in establishing temporary or reusable counters within macros. *expression* must be absolute and forward references are allowed.

Example

```
COUNT .SET 0 ; Initialize count. Later on you can  
      ; assign other values to the symbol
```

Related Information

[.EQU](#) (Set permanent value to a symbol)

.SIZE

Syntax

```
.SIZE symbol,expression
```

Description

With the `.SIZE` directive you set the size of the specified *symbol* to the value represented by *expression*.

The `.SIZE` directive may occur anywhere in the source file unless the specified symbol is a function. In this case, the `.SIZE` directive must occur after the function has been defined.

Example

```
_MCS_str: .type    object    ; object _MCS_str  
         .size    _MCS_str,16 ; size of object  
         .word    80  
         .word    67  
         .word    80  
         .word    0
```

Related Information

`.TYPE` (Set symbol type)

.SPACE

Syntax

```
[label:] .SPACE expression
```

Description

The `.SPACE` directive reserves a block in memory. The reserved block of memory is not initialized to any value.

If you specify the optional *label*, it gets the value of the location counter at the start of the directive processing.

The *expression* specifies the number of words to be reserved, and how much the location counter will advance. The expression must evaluate to an integer greater than zero and cannot contain any forward references (symbols that have not yet been defined).

If you specify *label*, it gets the value of the location counter at the start of the directive processing.

Example

To reserve 12 words (not initialized) of memory in a RAM data section:

```
        .sdecl  ".mcsdata.data"
        .sect   ".mcsdata.data"
uninit  .SPACE 12      ; Sample buffer
```

Related Information

[.WORD](#) (Define a constant word)

.TYPE

Syntax

symbol **.TYPE** *typeid*

Description

With the `.TYPE` directive you set a *symbol's* type to the specified value in the ELF symbol table. Valid symbol types are:

`FUNC` The symbol is associated with a function or other executable code.

`OBJECT` The symbol is associated with an object such as a variable, an array, or a structure.

`FILE` The symbol name represents the filename of the compilation unit.

Labels in code sections have the default type `FUNC`. Labels in data sections have the default type `OBJECT`.

Example

```
_MCS_Afunc: .type func
```

Related Information

`.SIZE` (Set symbol size)

.UNDEF

Syntax

```
.UNDEF symbol
```

Description

With the `.UNDEF` directive you can undefine a substitution string that was previously defined with the `.DEFINE` directive. The substitution string associated with *symbol* is released, and *symbol* will no longer represent a valid `.DEFINE` substitution or macro.

The assembler issues a warning if you undefine a non-existing symbol.

The assembler does not allow a label with this directive.

Example

The following example undefines the `LEN` substitution string that was previously defined with the `.DEFINE` directive:

```
.UNDEF LEN
```

Related Information

[.DEFINE](#) (Define a substitution string)

.WARNING

Syntax

```
.WARNING {str|exp}[,{str|exp}]...
```

Description

With the `.WARNING` directive you tell the assembler to print a warning message to `stderr` during the assembling process.

An arbitrary number of strings and expressions, in any order but separated by commas with no intervening white space, can be specified to describe the nature of the generated warning. If you use expressions, the assembler outputs the result. The assembler outputs a space between each argument.

The total warning count will be incremented as with any other warning. The `.WARNING` directive is for example useful in combination with conditional assembly to indicate which part is assembled. The assembling process proceeds normally after the message has been printed.

This directive has no effect on the exit code of the assembler, unless you use the [assembler option `--warnings-as-errors`](#). In that case the assembler exits with exit code 1 (an error).

A label is not allowed with this directive.

Example

```
.WARNING 'Parameter out of range'
```

This results in the warning:

```
W144: ["filename" line] Parameter out of range
```

Related Information

[.FAIL](#) (Programmer generated error)

[.MESSAGE](#) (Programmer generated message)

.WEAK

Syntax

```
.WEAK symbol [,symbol]...
```

Description

With the `.WEAK` directive you mark one or more symbols as 'weak'. The *symbol* can be defined in the same module with the `.GLOBAL` directive or the `.EXTERN` directive. If the symbol does not already exist, it will be created.

A 'weak' external reference is resolved by the linker when a global (or weak) definition is found in one of the object files. However, a weak reference will not cause the extraction of a module from a library to resolve the reference.

You can overrule a weak definition with a `.GLOBAL` definition in another module. The linker will not complain about the duplicate definition, and ignore the weak definition.

Only program labels and symbols defined with `.EQU` can be made weak.

Example

```
LOOPA .EQU 1           ; definition of symbol LOOPA
      .GLOBAL LOOPA   ; LOOPA will be globally
                      ; accessible by other modules
      .WEAK LOOPA     ; mark symbol LOOPA as weak
```

Related Information

[.EXTERN](#) (Import global section symbol)

[.GLOBAL](#) (Declare global section symbol)

.WORD

Syntax

```
[label:] .WORD argument[,argument]. . .
```

Description

With the `.WORD` directive the assembler allocates and initializes one word (32 bits) of memory for each *argument*.

If you specify the optional *label*, it gets the value of the location counter at the start of the directive processing.

An *argument* can be a single- or multiple-character string constant, an expression or empty.

Multiple arguments are stored in sets of four bytes. One or more arguments can be null (indicated by two adjacent commas), in which case the corresponding byte location will be filled with zeros.

The value of the arguments must be in range with the size of the directive; floating-point numbers are not allowed. If the evaluated argument is too large to be represented in a word, the assembler issues a warning and truncates the value.

String constants

Single-character strings are stored in the most significant byte of a word, where the lower seven bits in that byte represent the ASCII value of the character, for example:

```
.WORD 'R' ; = 0x52000000
```

Multiple-character strings are stored in consecutive byte addresses, as shown below. The standard C language escape characters like `\n` are permitted.

```
.WORD 'ABCD' ; = 0x44434241
```

Related Information

`.SPACE` (Define Storage)

2.9.2. Assembler Controls

Controls start with a **\$** as the first character on the line. Unknown controls are ignored after a warning is issued.

Overview of assembler listing controls

Control	Description
<code>\$LIST ON/OFF</code>	Print / do not print source lines to list file
<code>\$PAGE</code>	Generate form feed in list file
<code>\$PAGE settings</code>	Define page layout for assembly list file
<code>\$PRCTL</code>	Send control string to printer
<code>\$STITLE</code>	Set program subtitle in header of assembly list file
<code>\$TITLE</code>	Set program title in header of assembly list file

Overview of miscellaneous assembler controls

Control	Description
<code>\$CASE ON/OFF</code>	Case sensitive user names ON/OFF
<code>\$DEBUG ON/OFF</code>	Generation of symbolic debug ON/OFF
<code>\$IDENT LOCAL/GLOBAL</code>	Assembler treats labels by default as local or global
<code>\$OBJECT</code>	Alternative name for the generated object file
<code>\$WARNING OFF [num]</code>	Suppress all or some warnings

\$CASE

Syntax

```
$CASE ON  
$CASE OFF
```

Default

```
$CASE ON
```

Description

With the `$CASE ON` and `$CASE OFF` controls you specify whether the assembler operates in case sensitive mode or not. By default the assembler operates in case sensitive mode. This means that all user-defined symbols and labels are treated case sensitive, so `LAB` and `Lab` are distinct.

Note that the instruction mnemonics, register names, directives and controls are always treated case insensitive.

Example

```
;begin of source  
$CASE OFF ; assembler in case insensitive mode
```

Related Information

Assembler option **--case-insensitive**

\$DEBUG

Syntax

```
$DEBUG ON  
$DEBUG OFF
```

Default

```
$DEBUG OFF
```

Description

With the `$DEBUG ON` and `$DEBUG OFF` controls you turn the generation of debug information on or off. (`$DEBUG ON` is similar to the assembler option `--debug-info=+asm,+local (-gal)`).

Example

```
;begin of source  
$DEBUG ON ; generate local symbols debug information
```

Related Information

Assembler option `--debug-info`

\$IDENT

Syntax

```
$IDENT LOCAL  
$IDENT GLOBAL
```

Default

```
$IDENT LOCAL
```

Description

With the controls `$IDENT LOCAL` and `$IDENT GLOBAL` you tell the assembler how to treat symbols that you have not specified explicitly as local or global with the assembler directives `.LOCAL` or `.GLOBAL`.

By default the assembler treats all symbols as local symbols unless you have defined them to be global explicitly.

Example

```
;begin of source  
$IDENT GLOBAL ; assembly labels are global by default
```

Related Information

Assembler directive **`.GLOBAL`**

Assembler directive **`.LOCAL`**

Assembler option **`--symbol-scope`**

\$LIST ON/OFF

Syntax

```
$LIST ON
$LIST OFF
```

Default

```
$LIST ON
```

Description

If you generate a list file with the assembler option **--list-file**, you can use the `$LIST ON` and `$LIST OFF` controls to specify which source lines the assembler must write to the list file. Without the assembler option **--list-file** these controls have no effect. The controls take effect starting at the next line.

The `$LIST ON` control actually increments a counter that is checked for a positive value and is symmetrical with respect to the `$LIST OFF` control. Note the following sequence:

```
; Counter value currently 1
$LIST ON      ; Counter value = 2
$LIST ON      ; Counter value = 3
$LIST OFF     ; Counter value = 2
$LIST OFF     ; Counter value = 1
```

The listing still would not be disabled until another `$LIST OFF` control was issued.

Example

```
.SDECL ".mcstext.code",code
.SECT  ".mcstext.code"
... ; source line in list file
$LIST OFF
... ; source line not in list file
$LIST ON
... ; source line also in list file
```

Related Information

Assembler option **--list-file**

Assembler function **@LST()**

\$OBJECT

Syntax

```
$OBJECT "file"  
$OBJECT OFF
```

Default

```
$OBJECT
```

Description

With the `$OBJECT` control you can specify an alternative name for the generated object file. With the `$OBJECT OFF` control, the assembler does not generate an object file at all.

Example

```
;Begin of source  
$object "x1.o"           ; generate object file x1.o
```

Related Information

Assembler option **--output**

\$PAGE

Syntax

```
$PAGE [pagewidth[,pagelength[,blankleft[,blanktop[,blankbtm]]]]
```

Default

```
$PAGE 132,72,0,0,0
```

Description

If you generate a list file with the assembler option **--list-file**, you can use the `$PAGE` control to format the generated list file.

The arguments may be any positive absolute integer expression, and must be separated by commas.

<i>pagewidth</i>	Number of columns per line. The default is 132, the minimum is 40.
<i>pagelength</i>	Total number of lines per page. The default is 72, the minimum is 10. As a special case, a page length of 0 turns off page breaks.
<i>blankleft</i>	Number of blank columns at the left of the page. The default is 0, the minimum is 0, and the maximum must maintain the relationship: <i>blankleft</i> < <i>pagewidth</i> .
<i>blanktop</i>	Number of blank lines at the top of the page. The default is 0, the minimum is 0 and the maximum must be a value so that $(blanktop + blankbtm) \leq (pagelength - 10)$.
<i>blankbtm</i>	Number of blank lines at the bottom of the page. The default is 0, the minimum is 0 and the maximum must be a value so that $(blanktop + blankbtm) \leq (pagelength - 10)$.

If you use the `$PAGE` control without arguments, it causes a 'formfeed': the next source line is printed on the next page in the list file. The `$PAGE` control itself is not printed.

Example

```
$PAGE          ; formfeed, the next source line is printed
                ; on the next page in the list file.
```

```
$PAGE 96       ; set page width to 96. Note that you can
                ; omit the last four arguments.
```

```
$PAGE ,,,3,3   ; use 3 line top/bottom margins.
```

Related Information

Assembler option **--list-file**

\$PRCTL

Syntax

\$PRCTL *exp* | *string* [, *exp* | *string*] ...

Description

If you generate a list file with the assembler option **--list-file**, you can use the **\$PRCTL** control to send control strings to the printer.

The **\$PRCTL** control simply concatenates its arguments and sends them to the listing file (the control line itself is not printed unless there is an error).

You can specify the following arguments:

expr A byte expression which may be used to encode non-printing control characters, such as ESC.

string An assembler string, which may be of arbitrary length, up to the maximum assembler-defined limits.

The **\$PRCTL** control can appear anywhere in the source file; the assembler sends out the control string at the corresponding place in the listing file.

If a **\$PRCTL** control is the last line in the last input file to be processed, the assembler insures that all error summaries, symbol tables, and cross-references have been printed before sending out the control string. In this manner, you can use a **\$PRCTL** control to restore a printer to a previous mode after printing is done.

Similarly, if the **\$PRCTL** control appears as the first line in the first input file, the assembler sends out the control string before page headings or titles.

Example

```
$PRCTL $1B,'E' ; Reset HP LaserJet printer
```

Related Information

Assembler option **--list-file**

\$STITLE

Syntax

```
$STITLE "string"
```

Default

```
$STITLE ""
```

Description

If you generate a list file with the assembler option **--list-file**, you can use the `$STITLE` control to specify the program subtitle which is printed at the top of all succeeding pages in the assembler list file below the title.

The specified subtitle is valid until the assembler encounters a new `$STITLE` control. By default, the subtitle is empty.

The `$STITLE` control itself will not be printed in the source listing.

If the page width is too small for the title to fit in the header, it will be truncated.

Example

```
$TITLE    'This is the title'  
$STITLE  'This is the subtitle'
```

Related Information

Assembler option **--list-file**

Assembler control **\$TITLE**

\$TITLE

Syntax

```
$TITLE "string"
```

Default

```
$TITLE ""
```

Description

If you generate a list file with the assembler option **--list-file**, you can use the `$TITLE` control to specify the program title which is printed at the top of each page in the assembler list file.

The specified title is valid until the assembler encounters a new `$TITLE` control. By default, the title is empty.

The `$TITLE` control itself will not be printed in the source listing.

If the page width is too small for the title to fit in the header, it will be truncated.

Example

```
$TITLE 'This is the title'
```

Related Information

Assembler option **--list-file**

Assembler control **\$TITLE**

\$WARNING OFF

Syntax

```
$WARNING OFF [number]
```

Default

All warnings are reported.

Description

This control allows you to disable all or individual warnings. The *number* argument must be a valid warning message number.

Example

```
$WARNING OFF          ; all warning messages are suppressed
```

```
$WARNING OFF 135     ; suppress warning message 135
```

Related Information

Assembler option **--no-warnings**

2.10. Macro Operations

Macros provide a shorthand method for inserting a repeated pattern of code or group of instructions. You can define the pattern as a macro, and then call the macro at the points in the program where the pattern would repeat.

Some patterns contain variable entries which change for each repetition of the pattern. Others are subject to conditional assembly.

When a macro is called, the assembler executes the macro and replaces the call by the resulting in-line source statements. 'In-line' means that all replacements act as if they are on the same line as the macro call. The generated statements may contain substitutable arguments. The statements produced by a macro can be any processor instruction, almost any assembler directive, or any previously-defined macro. Source statements resulting from a macro call are subject to the same conditions and restrictions as any other statements.

Macros can be nested. The assembler processes nested macros when the outer macro is expanded.

2.10.1. Defining a Macro

The first step in using a macro is to define it.

The definition of a macro consists of three parts:

- *Header*, which assigns a name to the macro and defines the arguments (`.MACRO` directive).
- *Body*, which contains the code or instructions to be inserted when the macro is called.
- *Terminator*, which indicates the end of the macro definition (`.ENDM` directive).

A macro definition takes the following form:

```
macro_name .MACRO [argument[,argument]...]
...
macro_definition_statements
...
.ENDM
```

For more information on the definition see the description of the [.MACRO directive](#).

The `.DUP`, `.DUPA`, `.DUPC`, and `.DUPF` directives are specialized macro forms to repeat a block of source statements. You can think of them as a simultaneous definition and call of an unnamed macro. The source statements between the `.DUP`, `.DUPA`, `.DUPC`, and `.DUPF` directives and the `.ENDM` directive follow the same rules as macro definitions.

2.10.2. Calling a Macro

To invoke a macro, construct a source statement with the following format:

```
[label] macro_name [argument[,argument]...] [; comment]
```

where,

<i>label</i>	An optional label that corresponds to the value of the location counter at the start of the macro expansion.
<i>macro_name</i>	The name of the macro. This may not start in the first column.
<i>argument</i>	One or more optional, substitutable arguments. Multiple arguments must be separated by commas.
<i>comment</i>	An optional comment.

The following applies to macro arguments:

- Each argument must correspond one-to-one with the formal arguments of the macro definition. If the macro call does not contain the same number of arguments as the macro definition, the assembler issues a warning.
- If an argument has an embedded comma or space, you must surround the argument by single quotes (').
- You can declare a macro call argument as null in three ways:

- enter delimiting commas in succession with no intervening spaces

```
macroname ARG1,,ARG3 ; the second argument is a null argument
```

- terminate the argument list with a comma, the arguments that normally would follow, are now considered null

```
macroname ARG1, ; the second and all following arguments are null
```

- declare the argument as a null string

- No character is substituted in the generated statements that reference a null argument.

2.10.3. Using Operators for Macro Arguments

The assembler recognizes certain text operators within macro definitions which allow text substitution of arguments during macro expansion. You can use these operators for text concatenation, numeric conversion, and string handling.

Operator	Name	Description
\	Macro argument concatenation	Concatenates a macro argument with adjacent alphanumeric characters.
?	Return decimal value of symbol	Substitutes the <i>?symbol</i> sequence with a character string that represents the decimal value of the symbol.
%	Return hex value of symbol	Substitutes the <i>%symbol</i> sequence with a character string that represents the hexadecimal value of the symbol.
"	Macro string delimiter	Allows the use of macro arguments as literal strings.
^	Macro local label override	Prevents name mangling on labels in macros.

**Example: Argument Concatenation Operator - **

Consider the following macro definition:

```
MAC_A .MACRO reg,val
    movl r\reg,val
    .ENDM
```

The macro is called as follows:

```
MAC_A 0,1
```

The macro expands as follows:

```
movl r0,1
```

The macro preprocessor substitutes the character '0' for the argument `reg`, and the character '1' for the argument `val`. The concatenation operator (`\`) indicates to the macro preprocessor that the substitution characters for the arguments are to be concatenated with the character 'r'.

Without the `\` operator the macro would expand as:

```
movl rreg,1
```

which results in an assembler error (invalid operand).

Example: Decimal Value Operator - ?

Instead of substituting the formal arguments with the actual macro call arguments, you can also use the value of the macro call arguments.

Consider the following source code that calls the macro `MAC_A` after the argument `AVAL` has been set to 1.

```
AVAL .SET 1
    MAC_A 0,AVAL
```

If you want to replace the argument `val` with the value of `AVAL` rather than with the literal string 'AVAL', you can use the `?` operator and modify the macro as follows:

```
MAC_A .MACRO reg,val
    movl r\reg,?val
    .ENDM
```

Example: Hex Value Operator - %

The percent sign (`%`) is similar to the standard decimal value operator (`?`) except that it returns the hexadecimal value of a symbol.

Consider the following macro definition:

```
GEN_LAB .MACRO LAB,VAL,STMT
LAB\%VAL STMT
.ENDM
```

The macro is called after NUM has been set to 10:

```
NUM .SET 10
GEN_LAB HEX,NUM,NOP
```

The macro expands as follows:

```
HEXA NOP
```

The %VAL argument is replaced by the character 'A' which represents the hexadecimal value 10 of the argument VAL.

Example: Argument String Operator - "

To generate a literal string, enclosed by single quotes ('), you must use the argument string operator (") in the macro definition.

Consider the following macro definition:

```
STR_MAC .MACRO STRING
.WORD "STRING"
.ENDM
```

The macro is called as follows:

```
STR_MAC ABCD
```

The macro expands as follows:

```
.WORD 'ABCD'
```

Within double quotes .DEFINE directive definitions can be expanded. Take care when using constructions with single quotes and double quotes to avoid inappropriate expansions. Since .DEFINE expansion occurs before macro substitution, any .DEFINE symbols are replaced first within a macro argument string:

```
.DEFINE LONG 'short'
STR_MAC .MACRO STRING
.MESSAGE 'This is a LONG STRING'
.MESSAGE "This is a LONG STRING"
.ENDM
```

If the macro is called as follows:

```
STR_MAC sentence
```

it expands as:

```
.MESSAGE 'This is a LONG STRING'
.MESSAGE 'This is a short sentence'
```

Macro Local Label Override Operator - ^

If you use labels in macros, the assembler normally generates another unique name for the labels (such as LAB__M_L000001).

The macro ^-operator prevents name mangling on macro local labels.

Consider the following macro definition:

```
STA_Z .EQU    5

INIT  .MACRO  ARG, CNT
      MOV     R5, 0x1
^LAB:
      .WORD   ARG
      ADD     R5, 0x1
      ATUL    R5, CNT
      JBC     STA, STA_Z, ^LAB
      .ENDM
```

The macro is called as follows:

```
INIT 2, 4
```

The macro expands as:

```
      MOV     R5, 0x1
LAB:
      .WORD   2
      ADD     R5, 0x1
      ATUL    R5, 4
      JBC     STA, STA_Z, LAB
```

If you would have omitted the ^ operator, the macro preprocessor would choose another name for LAB because the label already exists. The macro would expand like:

```
      MOV     R5, 0x1
LAB__M_L000001:
      .WORD   2
      ADD     R5, 0x1
      ATUL    R5, 4
      JBC     STA, STA_Z, LAB__M_L000001
```

2.11. Generic Instructions

The assembler supports so-called 'generic instructions'. Generic instructions are pseudo instructions (no instructions from the instruction set). Depending on the situation in which a generic instruction is used, the assembler replaces the generic instruction with appropriate real assembly instruction(s).

If you select the MCS v1.0 core, the assembler supports the generic instructions MWRL and MWRIL that are replaced by MWR24 and MWRI24, so that code for newer cores can be built for the MCS v1.0 core.

If you select any other core than MCS v1.0, the assembler supports the generic instructions MWR24 and MWRI24 that are replaced by MWRL and MWRIL, so that code for the MCS v1.0 core can be built for newer cores.

MWRL generic

Convert MWRL to MWR24 on MCS v1.0.

Instruction	Replacement
MWRL <i>A,C</i>	MWR24 <i>A,C</i>

MWRIL generic

Convert MWRIL to MWRI24 on MCS v1.0.

Instruction	Replacement
MWRIL <i>A,B</i>	MWRI24 <i>A,B</i>

MWR24 generic

Convert MWR24 to MWRL on MCS v2.0 and later.

Instruction	Replacement
MWR24 <i>A,C</i>	MWRL <i>A,C</i>

MWRI24 generic

Convert MWRI24 to MWRIL on MCS v2.0 and later.

Instruction	Replacement
MWRI24 <i>A,B</i>	MWRIL <i>A,B</i>

Chapter 3. Using the C Compiler

This chapter describes the compilation process and explains how to call the C compiler.

The TASKING VX-toolset for MCS under Eclipse uses the TASKING makefile generator and make utility to build your entire embedded project, from C source till the final ELF/DWARF object file which serves as input for the debugger.

Although in Eclipse you cannot run the C compiler separately from the other tools, this section discusses the options that you can specify for the C compiler.

On the command line it is possible to call the C compiler separately from the other tools. However, it is recommended to use the control program for command line invocations of the toolset (see [Section 6.1, Control Program](#)). With the control program it is possible to call the entire toolset with only one command line.

The C compiler takes the following files for input and output:

This chapter first describes the compilation process which consists of a *frontend* and a *backend* part. Next it is described how to call the C compiler and how to use its options. An extensive list of all options and their descriptions is included in [Section 8.1, C Compiler Options](#). Finally, a few important basic tasks are described, such as including the C startup code and performing various optimizations.

3.1. Compilation Process

During the compilation of a C program, the C compiler runs through a number of phases that are divided into two parts: *frontend* and *backend*.

The backend part is not called for each C statement, but starts after a complete C module or set of modules has been processed by the frontend (in memory). This allows better optimization.

The C compiler requires only one pass over the input file which results in relative fast compilation.

Frontend phases

1. The preprocessor phase:

The preprocessor includes files and substitutes macros by C source. It uses only string manipulations on the C source. The syntax for the preprocessor is independent of the C syntax but is also described in the ISO/IEC 9899:1999(E) standard.

TASKING VX-toolset for MCS User Guide

2. The scanner phase:

The scanner converts the preprocessor output to a stream of tokens.

3. The parser phase:

The tokens are fed to a parser for the C grammar. The parser performs a syntactic and semantic analysis of the program, and generates an intermediate representation of the program. This code is called MIL (Medium level Intermediate Language).

4. The frontend optimization phase:

Target processor independent optimizations are performed by transforming the intermediate code.

Backend phases

1. Instruction selector phase:

This phase reads the MIL input and translates it into Low level Intermediate Language (LIL). The LIL objects correspond to a processor instruction, with an opcode, operands and information used within the C compiler.

2. Peephole optimizer/instruction scheduler/software pipelining phase:

This phase replaces instruction sequences by equivalent but faster and/or shorter sequences, rearranges instructions and deletes unnecessary instructions.

3. Register allocator phase:

This phase chooses a physical register to use for each virtual register. When there are not enough physical registers, virtual registers are spilled to the stack. Intermediate results of any optimization can live, for some time, on the stack or in physical registers.

4. The backend optimization phase:

Performs target processor independent and dependent optimizations which operate on the Low level Intermediate Language.

5. The code generation/formatter phase:

This phase reads through the LIL operations to generate assembly language output.

3.2. Calling the C Compiler

The TASKING VX-toolset for MCS under Eclipse uses the TASKING makefile generator and make utility to build your entire project. After you have built your project, the output files are available in a subdirectory of your project directory, depending on the active configuration you have set in the **C/C++ Build » Settings** page of the **Project » Properties for** dialog.

Building a project under Eclipse

You have several ways of building your project:

- Build Selected File(s) (🔗). This compiles and assembles the selected file(s) without calling the linker.
 1. In the C/C++ Projects view, select the files you want to compile.
 2. Right-click in the C/C++ Projects view and select **Build Selected File(s)**.
- Build Individual Project (🔗).

To build individual projects incrementally, select **Project » Build project**.
- Rebuild Project (🔗). This builds every file in the project whether or not a file has been modified since the last build. A rebuild is a clean followed by a build.
 1. Select **Project » Clean...**
 2. Enable the option **Start a build immediately** and click **OK**.
- Build Automatically. This performs a build of all projects whenever any project file is saved, such as your makefile.

This way of building is not recommended for C/C++ development, but to enable this feature select **Project » Build Automatically** and ensure there is a check mark beside the **Build Automatically** menu item. In order for this option to work, you must also enable option **Build on resource save (Auto build)** on the **Behavior** tab of the **C/C++ Build** page of the **Project » Properties for** dialog.

See also [Chapter 9, Influencing the Build Time](#).

Select a target processor (core)

Processor options affect the invocation of all tools in the toolset. In Eclipse you need to set them for each configuration. Based on the target processor, the compiler includes a special function register file. This is a regular include file which enables you to use virtual registers that are located in memory.

You can specify the target processor when you create a new project with the New C Project wizard (**File » New » TASKING MCS C Project**), but you can always change the processor in the project properties dialog.

1. From the **Project** menu, select **Properties for**

The Properties dialog appears.
2. In the left pane, expand **C/C++ Build** and select **Processor**.

In the right pane the Processor page appears.
3. From the **Configuration** list, select a configuration or select [All configurations].
4. From the **Processor selection** list, select a processor.

To access the C compiler options

1. From the **Project** menu, select **Properties for**
The Properties dialog appears.
2. In the left pane, expand **C/C++ Build** and select **Settings**.
In the right pane the Settings appear.
3. From the **Configuration** list, select a configuration or select [All configurations].
4. On the Tool Settings tab, select **C Compiler**.
5. Select the sub-entries and set the options in the various pages.

Note that the C compiler options are used to create an object file from a C file. The options you enter in the Assembler page are not only used for hand-coded assembly files, but also for intermediate assembly files.

Note that when you click **Restore Defaults** to restore the default tool options, as a side effect the processor is also reset to its default value on the **Processor** page (**C/C++ Build » Processor**).

You can find a detailed description of all C compiler options in [Section 8.1, C Compiler Options](#).

Invocation syntax on the command line:

```
cmcs [ [option]... [file]... ]...
```

3.3. How the Compiler Searches Include Files

When you use include files (with the `#include` statement), you can specify their location in several ways. The compiler searches the specified locations in the following order:

1. If the `#include` statement contains an absolute pathname, the compiler looks for this file. If no path or a relative path is specified, the compiler looks in the same directory as the source file. This is only possible for include files that are enclosed in "".

This first step is not done for include files enclosed in <>.

2. When the compiler did not find the include file, it looks in the directories that are specified in the **C Compiler » Include Paths** page in the **C/C++ Build » Settings » Tool Settings** tab of the Project Properties dialog (equivalent to `option --include-directory (-I)`).
3. When the compiler did not find the include file (because it is not in the specified include directory or because no directory is specified), it looks in the path(s) specified in the environment variable `CMCSINC`.

4. When the compiler still did not find the include file, it finally tries the default include directory relative to the installation directory (unless you specified [option `--no-stdinc`](#)).

Example

Suppose that the C source file `test.c` contains the following lines:

```
#include <stdio.h>
#include "myinc.h"
```

You can call the compiler as follows:

```
cmcs -Imyinclude test.c
```

First the compiler looks for the file `stdio.h` in the directory `myinclude` relative to the current directory. If it was not found, the compiler searches in the environment variable `CMCSINC` and then in the default `include` directory.

The compiler now looks for the file `myinc.h`, in the directory where `test.c` is located. If the file is not there the compiler searches in the directory `myinclude`. If it was still not found, the compiler searches in the environment variable `CMCSINC` and then in the default `include` directory.

3.4. Compiling for Debugging

Compiling your files is the first step to get your application ready to run on a target. However, during development of your application you first may want to debug your application.

To create an object file that can be used for debugging, you must instruct the compiler to include symbolic debug information in the source file.

To include symbolic debug information

1. From the **Project** menu, select **Properties for**
The Properties dialog appears.
2. In the left pane, expand **C/C++ Build** and select **Settings**.
In the right pane the Settings appear.
3. On the Tool Settings tab, select **C Compiler » Debugging**.
4. Select **Default** in the **Generate symbolic debug information** box.

Debug and optimizations

Due to different compiler optimizations, it might be possible that certain debug information is optimized away. Therefore, if you encounter strange behavior during debugging it might be necessary to reduce the optimization level, so that the source code is still suitable for debugging. For more information on optimization see [Section 3.5, Compiler Optimizations](#).

Invocation syntax on the command line

The invocation syntax on the command line is:

```
cmcs -g file.c
```

3.5. Compiler Optimizations

The compiler has a number of optimizations which you can enable or disable.

1. From the **Project** menu, select **Properties for**
The Properties dialog appears.
2. In the left pane, expand **C/C++ Build** and select **Settings**.
In the right pane the Settings appear.
3. From the **Configuration** list, select a configuration or select [All configurations].
4. On the Tool Settings tab, select **C Compiler » Optimization**.
5. Select an optimization level in the **Optimization level** box.

or:

In the **Optimization level** box select **Custom optimization** and enable the optimizations you want on the Custom optimization page.

Optimization levels

The TASKING C compiler offers four optimization levels and a custom level, at each level a specific set of optimizations is enabled.

- **Level 0 - No optimization:** No optimizations are performed. The compiler tries to achieve a 1-to-1 resemblance between source code and produced code. Expressions are evaluated in the order written in the source code, associative and commutative properties are not used.
- **Level 1 - Optimize:** Enables optimizations that do not affect the debug-ability of the source code. Use this level when you encounter problems during debugging your source code with optimization level 2.
- **Level 2 - Optimize more (default):** Enables more optimizations to reduce the memory footprint and/or execution time. This is the default optimization level.
- **Level 3 - Optimize most:** This is the highest optimization level. Use this level when your program/hardware has become too slow to meet your real-time requirements.
- **Custom optimization:** you can enable/disable specific optimizations on the Custom optimization page.

Optimization pragmas

If you specify a certain optimization, all code in the module is subject to that optimization. Within the C source file you can overrule the C compiler options for optimizations with `#pragma optimize flag` and `#pragma endoptimize`. Nesting is allowed:

```
#pragma optimize e      /* Enable expression
...                    simplification          */
... C source ...
...
#pragma optimize c      /* Enable common expression
...                    elimination. Expression
... C source ...       simplification still enabled */
...
#pragma endoptimize    /* Disable common expression
...                    elimination          */
#pragma endoptimize    /* Disable expression
...                    simplification      */
```

The compiler optimizes the code between the pragma pair as specified.

You can enable or disable the optimizations described in the following subsection. The command line option for each optimization is given in brackets.

3.5.1. Generic Optimizations (frontend)

Common subexpression elimination (CSE) (option -Oc/-OC)

The compiler detects repeated use of the same (sub-)expression. Such a "common" expression is replaced by a variable that is initialized with the value of the expression to avoid recomputation. This method is called common subexpression elimination (CSE).

A CSE can live in a register, on stack or can be recomputed when required.

Expression simplification (option -Oe/-OE)

Multiplication by 0 or 1 and additions or subtractions of 0 are removed. Such useless expressions may be introduced by macros or by the compiler itself (for example, array subscripting).

Constant propagation (option -Op/-OP)

A variable with a known value is replaced by that value.

Automatic function inlining (option -Oi/-OI)

Small functions that are not too often called, are inlined. This reduces execution time at the cost of code size.

Control flow simplification (option -Of/-OF)

A number of techniques to simplify the flow of the program by removing unnecessary code and reducing the number of jumps. For example:

- *Switch optimization*: A number of optimizations of a switch statement are performed, such as removing redundant case labels or even removing an entire switch.
- *Jump chaining*: A (conditional) jump to a label which is immediately followed by an unconditional jump may be replaced by a jump to the destination label of the second jump. This optimization speeds up execution.
- *Conditional jump reversal*: A conditional jump over an unconditional jump is transformed into one conditional jump with the jump condition reversed. This reduces both the code size and the execution time.
- *Dead code elimination*: Code that is never reached, is removed. The compiler generates a warning messages because this may indicate a coding error.

Subscript strength reduction (option -Os/-OS)

An array or pointer subscripted with a loop iterator variable (or a simple linear function of the iterator variable), is replaced by the dereference of a pointer that is updated whenever the iterator is updated.

Loop transformations (option -Ol/-OL)

Transform a loop with the entry point at the bottom, to a loop with the entry point at the top. This enables constant propagation in the initial loop test and code motion of loop invariant code by the CSE optimization.

Forward store (option -Oo/-OO)

A temporary variable is used to cache multiple assignments (stores) to the same non-automatic variable.

3.5.2. Core Specific Optimizations (backend)

Coalescer (option -Oa/-OA)

The coalescer seeks for possibilities to reduce the number of moves (MOV instruction) by smart use of registers. This optimizes both speed and code size.

Interprocedural register optimization (option -Ob/-OB)

Register allocation is improved by taking note of register usage in functions called by a given function.

Peephole optimizations (option -Oy/-OY)

The generated assembly code is improved by replacing instruction sequences by equivalent but faster and/or shorter sequences, or by deleting unnecessary instructions.

Unroll small loops (option -Ou/-OU)

To reduce the number of branches, short loops are eliminated by replacing them with a number of copies.

Generic assembly optimizations (option -Og/-OG)

A set of optimizations on the generated assembly code that increase speed and decrease code size, similar to peephole optimizations applied within and across basic blocks. The set includes but is not limited to:

- removal of unused code
- removal of superfluous code
- loop optimizations
- flow optimizations

Shrink wrapping (option -Oh/-OH)

The shrink wrapper tries to move code from the function's prologue/epilogue to a conditional path. The prologue/epilogue code is then only executed when necessary. For example:

```
extern int e( int * p );

int g;
int h;

int f( int p )
{
    int r;
    int a;
    int b;

    r = 0;
    if ( p != 0 )
    {
        a = g;
        b = h;

        e( &a );

        r = a + b;
    }
    return r;
}
```

When compiled with the shrink wrapper disabled (**-OH**) this results in:

```
f:      .type   func
       .addl  r7,#8      ; function prologue always executed
```

```

        mwri    r6,r7,#-4
;-----
        movl   r5,#0
        atul   r2,#0
        jbs    sta,#5,.L2    ; conditional branch
        mrd    r5,g
        mwri   r5,r7
        mrd    r6,h
        mov    r2,r7
        call   e
        mrdi   r5,r7
        add    r5,r6
.L2:
        mov    r2,r5
;-----
        mrdi   r6,r7,#-4    ; function epilogue always executed
        subl   r7,#8

```

When the shrink wrapper is enabled the function's prologue/epilogue code is moved under the `if()` statement. By doing so, the stack pointer `r7` will only be updated and register `r6` will only be saved/restored when the assignments and the call to function `e()` are really executed, and the function will execute faster when parameter `p == 0`. With the shrink wrapper enabled (**-Oh**) this results in:

```

f:      .type   func
        movl   r5,#0
        atul   r2,#0
        jbs    sta,#5,.L2    ; conditional branch
;-----
        addl   r7,#8        ; function prologue conditionally executed
        mwri   r6,r7,#-4
;-----
        mrd    r5,g
        mwri   r5,r7
        mrd    r6,h
        mov    r2,r7
        call   e
        mrdi   r5,r7
        add    r5,r6
;-----
        mrdi   r6,r7,#-4    ; function epilogue conditionally executed
        subl   r7,#8
;-----
.L2:
        mov    r2,r5

```

3.5.3. Optimize for Code Size or Execution Speed

You can tell the compiler to focus on execution speed or code size during optimizations. You can do this by specifying a size/speed trade-off level from 0 (speed) to 4 (size). This trade-off does not turn optimization phases on or off. Instead, its level is a weight factor that is used in the different optimization phases to

influence the heuristics. The higher the level, the more the compiler focusses on code size optimization. To choose a trade-off value read the description below about which optimizations are affected and the impact of the different trade-off values.

Note that the trade-off settings are directions and there is no guarantee that these are followed. The compiler may decide to generate different code if it assessed that this would improve the result.

Optimization hint: Optimizing for size has a speed penalty and vice versa. The advice is to optimize for size by default and only optimize those areas for speed that are critical for the application with respect to speed. Using the tradeoff options **-t0**, **-t1** and **-t2** globally for the application is not recommended.

To specify the size/speed trade-off optimization level:

1. From the **Project** menu, select **Properties for**
The Properties dialog appears.
2. In the left pane, expand **C/C++ Build** and select **Settings**.
In the right pane the Settings appear.
3. On the Tool Settings tab, select **C Compiler » Optimization**.
4. Select a trade-off level in the **Trade-off between speed and size** box.

See also [C compiler option --tradeoff \(-t\)](#)

Instruction Selection

Trade-off levels 0, 1 and 2: the compiler selects the instructions with the smallest number of cycles.

Trade-off levels 3 and 4: the compiler selects the instructions with the smallest number of bytes.

Loop Optimization

For a top-loop, the loop is entered at the top of the loop. A bottom-loop is entered at the bottom. Every loop has a test and a jump at the bottom of the loop, otherwise it is not possible to create a loop. Some top-loops also have a conditional jump before the loop. This is only necessary when the number of loop iterations is unknown. The number of iterations might be zero, in this case the conditional jump jumps over the loop.

Bottom loops always have an unconditional jump to the loop test at the bottom of the loop.

Trade-off value	Try to rewrite top-loops to bottom-loops	Optimize loops for size/speed
0	no	speed
1	yes	speed
2	yes	speed

TASKING VX-toolset for MCS User Guide

Trade-off value	Try to rewrite top-loops to bottom-loops	Optimize loops for size/speed
3	yes	size
4	yes	size

Example:

```
unsigned int a[100];

void i( unsigned int l, unsigned int m )
{
    unsigned int i;
    for ( i = m; i < l; i += 4 )
    {
        a[i] = 0;
    }
    return;
}
```

Coded as a bottom loop (compiled with **--tradeoff=4**) is:

```
        movl  r5,#a
        mov   r4,r3
        shl  r4,#2
        add  r5,r4
        movl  r4,#0
        jmp  .L2          ;; unconditional jump to loop test at bottom
.L3:
        mwri  r4,r5
        addl  r5,#16
        addl  r3,#4
.L2:
        ;; loop entry point
        atu  r3,r2
        jbs  sta,#4,.L3
        ret
```

Coded as a top loop (compiled with **--tradeoff=0**) is:

```
        movl  r5,#a
        mov   r4,r3
        shl  r4,#2
        add  r5,r4
        atu  r3,r2          ;; test for at least one loop iteration
        jbc  sta,#4,.L2    ;; can be omitted when number of iterations is known
        sub  r2,r3
        addl  r2,#3
        shr  r2,#2
        movl  r4,#0
.L3:
        ;; loop entry point
        mwri  r4,r5
```

```

    addl   r5,#16
    subl   r2,#1
    jbc    sta,#5,.L3
.L2:
    ret

```

Automatic Function Inlining

You can enable automatic function inlining with the option `--optimize=+inline (-Oi)` or by using `#pragma optimize +inline`. This option is also part of the `-O3` predefined option set.

When automatic inlining is enabled, you can use the options `--inline-max-incr` and `--inline-max-size` (or their corresponding pragmas `inline_max_incr` / `inline_max_size`) to control automatic inlining. By default their values are set to -1. This means that the compiler will select a value depending upon the selected trade-off level. The defaults are:

Trade-off value	inline-max-incr	inline-max-size
0	100	50
1	50	25
2	20	20
3	10	10
4	0	0

For example with trade-off value 1, the compiler inlines all functions that are smaller or equal to 25 internal compiler units. After that the compiler tries to inline even more functions as long as the function will not grow more than 50%.

When these options/pragmas are set to a value ≥ 0 , the specified value is used instead of the values from the table above.

Static functions that are called only once, are always inlined, independent of the values chosen for `inline-max-incr` and `inline-max-size`.

3.6. Static Code Analysis

Static code analysis (SCA) is a relatively new feature in compilers. Various approaches and algorithms exist to perform SCA, each having specific pros and cons.

SCA Implementation Design Philosophy

SCA is implemented in the TASKING compiler based on the following design criteria:

- An SCA phase does not take up an excessive amount of execution time. Therefore, the SCA can be performed during a normal edit-compile-debug cycle.
- SCA is implemented in the compiler front-end. Therefore, no new makefiles or work procedures have to be developed to perform SCA.

- The number of emitted false positives is kept to a minimum. A false positive is a message that indicates that a correct code fragment contains a violation of a rule/recommendation. A number of warnings is issued in two variants, one variant when it is *guaranteed* that the rule is violated when the code is executed, and the other variant when the rules is *potentially* violated, as indicated by a preceding warning message.

For example see the following code fragment:

```
extern int some_condition(int);
void f(void)
{
    char buf[10];
    int i;

    for (i = 0; i <= 10; i++)
    {
        if (some_condition(i))
        {
            buf[i] = 0; /* subscript may be out of bounds */
        }
    }
}
```

As you can see in this example, if `i=10` the array `buf[]` might be accessed beyond its upper boundary, depending on the result of `some_condition(i)`. If the compiler cannot determine the result of this function at run-time, the compiler issues the warning "subscript is *possibly* out of bounds" preceding the CERT warning "ARR35: do not allow loops to iterate beyond the end of an array". If the compiler can determine the result, or if the `if` statement is omitted, the compiler can guarantee that the "subscript is out of bounds".

- The SCA implementation has real practical value in embedded system development. There are no real objective criteria to measure this claim. Therefore, the TASKING compilers support well known standards for safety critical software development such as the MISRA guidelines for creating software for safety critical automotive systems and secure "CERT C Secure Coding Standard" released by CERT. CERT is founded by the US government and studies internet and networked systems security vulnerabilities, and develops information to improve security.

Effect of optimization level on SCA results

The SCA implementation in the TASKING compilers has the following limitations:

- Some violations of rules will only be detected when a particular optimization is enabled, because they rely on the analysis done for that optimization, or on the transformations performed by that optimization. In particular, the constant propagation and the CSE/PRE optimizations are required for some checks. It is preferred that you enable these optimizations. These optimizations are enabled with the default setting of the optimization level (**-O2**).
- Some checks require cross-module inspections and violations will only be detected when multiple source files are compiled and linked together by the compiler in a single invocation.

3.6.1. C Code Checking: CERT C

The CERT C Secure Coding Standard provides rules and recommendations for secure coding in the C programming language. The goal of these rules and recommendations is to eliminate insecure coding practices and undefined behaviors that can lead to exploitable vulnerabilities. The application of the secure coding standard will lead to higher-quality systems that are robust and more resistant to attack.

For details about the standard, see the [CERT C Secure Coding Standard](#) web site. For general information about CERT secure coding, see www.cert.org/secure-coding.

Versions of the CERT C standard

Version 1.0 of the CERT C Secure Coding Standard is available as a book by Robert C. Seacord [Addison-Wesley]. Whereas the web site is a wiki and reflects the latest information, the book serves as a fixed point of reference for the development of compliant applications and source code analysis tools.

The rules and recommendations supported by the TASKING compiler reflect the version of the CERT web site as of June 1 2009.

The following rules/recommendations implemented by the TASKING compiler, are not part of the book: [PRE11-C](#), [FLP35-C](#), [FLP36-C](#), [MSC32-C](#)

For a complete overview of the supported CERT C recommendations/rules by the TASKING compiler, see [Chapter 15, CERT C Secure Coding Standard](#).

Priority and Levels of CERT C

Each CERT C rule and recommendation has an assigned *priority*. Three values are assigned for each rule on a scale of 1 to 3 for

- severity - how serious are the consequences of the rule being ignored
 1. low (denial-of-service attack, abnormal termination)
 2. medium (data integrity violation, unintentional information disclosure)
 3. high (run arbitrary code)
- likelihood - how likely is it that a flaw introduced by ignoring the rule could lead to an exploitable vulnerability
 1. unlikely
 2. probable
 3. likely
- remediation cost - how expensive is it to comply with the rule
 1. high (manual detection and correction)
 2. medium (automatic detection and manual correction)

TASKING VX-toolset for MCS User Guide

3. low (automatic detection and correction)

The three values are then multiplied together for each rule. This product provides a measure that can be used in prioritizing the application of the rules. These products range from 1 to 27. Rules and recommendations with a priority in the range of 1-4 are level 3 rules (low severity, unlikely, expensive to repair flaws), 6-9 are level 2 (medium severity, probable, medium cost to repair flaws), and 12-27 are level 1 (high severity, likely, inexpensive to repair flaws).

The TASKING compiler checks most of the level 1 and some of the level 2 CERT C recommendations/rules.

For a complete overview of the supported CERT C recommendations/rules by the TASKING compiler, see [Chapter 15, CERT C Secure Coding Standard](#).

To apply CERT C code checking to your application

1. From the **Project** menu, select **Properties for**

The Properties dialog appears.

2. In the left pane, expand **C/C++ Build** and select **Settings**.

In the right pane the Settings appear.

3. On the Tool Settings tab, select **C Compiler » CERT C Secure Coding**.

4. Make a selection from the **CERT C secure code checking** list.

5. If you selected **Custom**, expand the **Custom CERT C** entry and enable one or more individual recommendations/rules.

On the command line you can use the option `--cert`.

```
cmcs --cert={all | name [-name], ...}
```

With `--diag=cert` you can see a list of the available checks, or you can use a three-letter mnemonic to list only the checks in a particular category. For example, `--diag=pre` lists all supported checks in the preprocessor category.

3.6.2. C Code Checking: MISRA C

The C programming language is a standard for high level language programming in embedded systems, yet it is considered somewhat unsuitable for programming safety-related applications. Through enhanced code checking and strict enforcement of best practice programming rules, TASKING MISRA C code checking helps you to produce more robust code.

MISRA C specifies a subset of the C programming language which is intended to be suitable for embedded automotive systems. It consists of a set of rules, defined in *MISRA-C:2004, Guidelines for the Use of the C Language in Critical Systems* (Motor Industry Research Association (MIRA), 2004).

The compiler also supports MISRA C:1998, the first version of MISRA C and MISRA C: 2012, the latest version of MISRA C. You can select the version with the following C compiler option:

```
--misrac-version=1998
--misrac-version=2004
--misrac-version=2012
```

In your C source files you can check against the MISRA C version used. For example:

```
#if __MISRA_C_VERSION__ == 1998
    ...
#elif __MISRA_C_VERSION__ == 2004
    ...
#elif __MISRA_C_VERSION__ == 2012
    ...
#endif
```

For a complete overview of all MISRA C rules, see [Chapter 16, MISRA C Rules](#).

Implementation issues

The MISRA C implementation in the compiler supports nearly all rules. Only a few rules are not supported because they address documentation, run-time behavior, or other issues that cannot be checked by static source code inspection, or because they require an application-wide overview.

During compilation of the code, violations of the enabled MISRA C rules are indicated with error messages and the build process is halted.

MISRA C rules are divided in mandatory rules, required rules and advisory rules. If rules are violated, errors are generated causing the compiler to stop. With the following options warnings, instead of errors, are generated:

```
--misrac-mandatory-warnings
--misrac-required-warnings
--misrac-advisory-warnings
```

Note that not all MISRA C violations will be reported when other errors are detected in the input source. For instance, when there is a syntax error, all semantic checks will be skipped, including some of the MISRA C checks. Also note that some checks cannot be performed when the optimizations are switched off.

Quality Assurance report

To ensure compliance to the MISRA C rules throughout the entire project, the TASKING linker can generate a MISRA C Quality Assurance report. This report lists the various modules in the project with the respective MISRA C settings at the time of compilation. You can use this in your company's quality assurance system to provide proof that company rules for best practice programming have been applied in the particular project.

To apply MISRA C code checking to your application

1. From the **Project** menu, select **Properties for**

TASKING VX-toolset for MCS User Guide

The Properties dialog appears.

2. In the left pane, expand **C/C++ Build** and select **Settings**.

In the right pane the Settings appear.

3. On the Tool Settings tab, select **C Compiler » MISRA C**.
4. Select the **MISRA C version** (1998, 2004 or 2012).
5. In the **MISRA C checking** box select a MISRA C configuration. Select a predefined configuration for conformance with the required rules in the MISRA C guidelines.
6. (Optional) In the **Custom 1998**, **Custom 2004** or **Custom 2012** entry, specify the individual rules.

On the command line you can use the option `--misrac`.

```
cmcs --misrac={all | number [-number], ...}
```

3.7. C Compiler Error Messages

The C compiler reports the following types of error messages in the Problems view of Eclipse.

F (Fatal errors)

After a fatal error the compiler immediately aborts compilation.

E (Errors)

Errors are reported, but the compiler continues compilation. No output files are produced unless you have set the C compiler option `--keep-output-files` (the resulting output file may be incomplete).

W (Warnings)

Warning messages do not result into an erroneous assembly output file. They are meant to draw your attention to assumptions of the compiler for a situation which may not be correct. You can control warnings in the **C/C++ Build » Settings » Tool Settings » C Compiler » Diagnostics** page of the **Project » Properties for** menu (C compiler option `--no-warnings`).

I (Information)

Information messages are always preceded by an error message. Information messages give extra information about the error.

S (System errors)

System errors occur when internal consistency checks fail and should never occur. When you still receive the system error message

```
S9##: internal consistency check failed - please report
```

please report the error number and as many details as possible about the context in which the error occurred.

Display detailed information on diagnostics

1. From the **Window** menu, select **Show View » Other » TASKING » Problems**.

The Problems view is added to the current perspective.

2. In the Problems view right-click on a message.

A popup menu appears.

3. Select **Detailed Diagnostics Info**.

A dialog box appears with additional information.

On the command line you can use the C compiler option **--diag** to see an explanation of a diagnostic message:

```
cmcs --diag=[format:]{all | number, ...}
```

Chapter 4. Using the Assembler

This chapter describes the assembly process and explains how to call the assembler.

The assembler converts hand-written or compiler-generated assembly language programs into machine language, resulting in object files in the ELF/DWARF object format.

The assembler takes the following files for input and output:

The following information is described:

- The assembly process.
- How to call the assembler and how to use its options. An extensive list of all options and their descriptions is included in [Section 8.2, *Assembler Options*](#).
- How to generate a list file.
- Types of assembler messages.

4.1. Assembly Process

The assembler generates relocatable output files with the extension `.o`. These files serve as input for the linker.

Phases of the assembly process

- Parsing of the source file: preprocessing of assembler directives and checking of the syntax of instructions
- Instruction grouping and reordering
- Generation of the relocatable object file and optionally a list file

The assembler integrates file inclusion and macro facilities. See [Section 2.10, *Macro Operations*](#) for more information.

4.2. Calling the Assembler

The TASKING VX-toolset for MCS under Eclipse uses the TASKING makefile generator and make utility to build your entire project. After you have built your project, the output files are available in a subdirectory of your project directory, depending on the active configuration you have set in the **C/C++ Build » Settings** page of the **Project » Properties for** dialog.

Building a project under Eclipse

You have several ways of building your project:

- Build Selected File(s) (🔗). This compiles and assembles the selected file(s) without calling the linker.
 1. In the C/C++ Projects view, select the files you want to compile.
 2. Right-click in the C/C++ Projects view and select **Build Selected File(s)**.

- Build Individual Project (🔗).

To build individual projects incrementally, select **Project » Build project**.

- Rebuild Project (🔗). This builds every file in the project whether or not a file has been modified since the last build. A rebuild is a clean followed by a build.

1. Select **Project » Clean...**
2. Enable the option **Start a build immediately** and click **OK**.

- Build Automatically. This performs a build of all projects whenever any project file is saved, such as your makefile.

This way of building is not recommended, but to enable this feature select **Project » Build Automatically** and ensure there is a check mark beside the **Build Automatically** menu item. In order for this option to work, you must also enable option **Build on resource save (Auto build)** on the **Behavior** tab of the **C/C++ Build** page of the **Project » Properties for** dialog.

Select a target processor (core)

Processor options affect the invocation of all tools in the toolset. In Eclipse you need to set them for each configuration.

1. From the **Project** menu, select **Properties for**

The Properties dialog appears.

2. In the left pane, expand **C/C++ Build** and select **Processor**.

In the right pane the Processor page appears.

3. From the **Configuration** list, select a configuration or select [All configurations].

4. From the **Processor selection** list, select a processor.

To access the assembler options

1. From the **Project** menu, select **Properties for**
The Properties dialog appears.
2. In the left pane, expand **C/C++ Build** and select **Settings**.
In the right pane the Settings appear.
3. From the **Configuration** list, select a configuration or select [All configurations].
4. On the Tool Settings tab, select **Assembler**.
5. Select the sub-entries and set the options in the various pages.

Note that the options you enter in the Assembler page are not only used for hand-coded assembly files, but also for the assembly files generated by the compiler.

Note that when you click **Restore Defaults** to restore the default tool options, as a side effect the processor is also reset to its default value on the **Processor** page (**C/C++ Build** » **Processor**).

You can find a detailed description of all assembler options in [Section 8.2, Assembler Options](#).

Invocation syntax on the command line:

```
asmcs [ [option]... [file]... ]...
```

The input file must be an assembly source file (.asm, .mcs or .src).

4.3. How the Assembler Searches Include Files

When you use include files (with the `.INCLUDE` directive), you can specify their location in several ways. The assembler searches the specified locations in the following order:

1. If the `.INCLUDE` directive contains an absolute path name, the assembler looks for this file. If no path or a relative path is specified, the assembler looks in the same directory as the source file.
2. When the assembler did not find the include file, it looks in the directories that are specified in the **Assembler** » **Include Paths** page in the **C/C++ Build** » **Settings** » **Tool Settings** tab of the Project Properties dialog (equivalent to `option --include-directory (-I)`).
3. When the assembler did not find the include file (because it is not in the specified include directory or because no directory is specified), it looks in the path(s) specified in the environment variable `ASMCSINC`.

4. When the assembler still did not find the include file, it finally tries the default include directory relative to the installation directory.

Example

Suppose that the assembly source file `test.asm` contains the following lines:

```
.INCLUDE 'myinc.inc'
```

You can call the assembler as follows:

```
asmcs -Imyinclude test.asm
```

First the assembler looks for the file `myinc.asm`, in the directory where `test.asm` is located. If the file is not there the assembler searches in the directory `myinclude`. If it was still not found, the assembler searches in the environment variable `ASMCSINC` and then in the default `include` directory.

4.4. Generating a List File

The list file is an additional output file that contains information about the generated code. You can customize the amount and form of information.

If the assembler generates errors or warnings, these are reported in the list file just below the source line that caused the error or warning.

To generate a list file

1. From the **Project** menu, select **Properties for**
The Properties dialog appears.
2. In the left pane, expand **C/C++ Build** and select **Settings**.
In the right pane the Settings appear.
3. On the Tool Settings tab, select **Assembler » List File**.
4. Enable the option **Generate list file**.
5. (Optional) Enable the options to include that information in the list file.

Example on the command line

The following command generates the list file `test.lst`:

```
asmcs -l test.asm
```

See [Section 11.1, Assembler List File Format](#), for an explanation of the format of the list file.

4.5. Assembler Error Messages

The assembler reports the following types of error messages in the Problems view of Eclipse.

F (Fatal errors)

After a fatal error the assembler immediately aborts the assembly process.

E (Errors)

Errors are reported, but the assembler continues assembling. No output files are produced unless you have set the `assembler option --keep-output-files` (the resulting output file may be incomplete).

W (Warnings)

Warning messages do not result into an erroneous assembly output file. They are meant to draw your attention to assumptions of the assembler for a situation which may not be correct. You can control warnings in the **C/C++ Build » Settings » Tool Settings » Assembler » Diagnostics** page of the **Project » Properties for** menu (`assembler option --no-warnings`).

Display detailed information on diagnostics

1. From the **Window** menu, select **Show View » Other » TASKING » Problems**.

The Problems view is added to the current perspective.

2. In the Problems view right-click on a message.

A popup menu appears.

3. Select **Detailed Diagnostics Info**.

A dialog box appears with additional information.

On the command line you can use the `assembler option --diag` to see an explanation of a diagnostic message:

```
asmcs --diag=[format:]{all | number, ...}
```

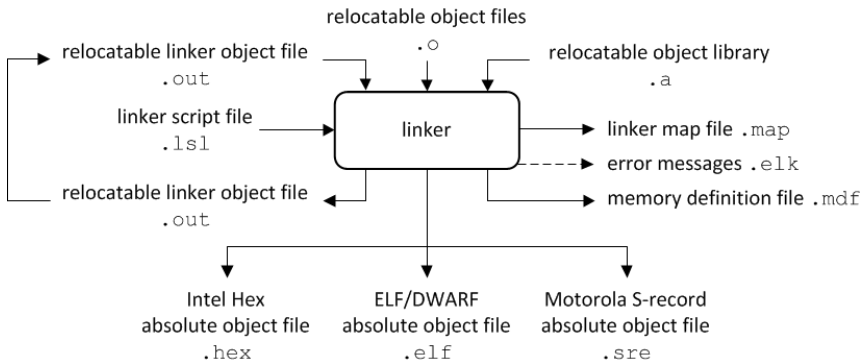

Chapter 5. Using the Linker

This chapter describes the linking process, how to call the linker and how to control the linker with a script file.

The TASKING linker is a combined linker/locator. The linker phase combines relocatable object files (.o files, generated by the assembler), and libraries into a single relocatable linker object file (.out). The locator phase assigns absolute addresses to the linker object file and creates an absolute object file which you can load into a target processor. From this point the term linker is used for the combined linker/locator.

The linker can simultaneously link and locate all programs for all cores available on a target board. The target board may be of arbitrary complexity. A simple target board may contain one standard processor with some external memory that executes one task. A complex target board may contain multiple standard processors and DSPs combined with configurable IP-cores loaded in an FPGA. Each core may execute a different program, and external memory may be shared by multiple cores.

The linker takes the following files for input and output:

This chapter first describes the linking process. Then it describes how to call the linker and how to use its options. An extensive list of all options and their descriptions is included in [Section 8.3, Linker Options](#).

To control the link process, you can write a script for the linker. This chapter shortly describes the purpose and basic principles of the Linker Script Language (LSL) on the basis of an example. A complete description of the LSL is included in Linker Script Language.

5.1. Linking Process

The linker combines and transforms relocatable object files (.o) into a single absolute object file. This process consists of two phases: the linking phase and the locating phase.

In the first phase the linker combines the supplied relocatable object files and libraries into a single relocatable object file. In the second phase, the linker assigns absolute addresses to the object file so it can actually be loaded into a target.

Terms used in the linking process

Term	Definition
Absolute object file	Object code in which addresses have fixed absolute values, ready to load into a target.
Address	A specification of a location in an address space.
Address space	The set of possible addresses. A core can support multiple spaces, for example in a Harvard architecture the addresses that identify the location of an instruction refer to <i>code</i> space, whereas addresses that identify the location of a data object refer to a <i>data</i> space.
Architecture	A description of the characteristics of a core that are of interest for the linker. This encompasses the address space(s) and the internal bus structure. Given this information the linker can convert logical addresses into physical addresses.
Copy table	A section created by the linker. This section contains data that specifies how the startup code initializes the data and BSS sections. For each section the copy table contains the following fields: <ul style="list-style-type: none"> • action: defines whether a section is copied or zeroed • destination: defines the section's address in RAM • source: defines the sections address in ROM, zero for BSS sections • length: defines the size of the section in MAUs of the destination space
Core	An instance of an architecture.
Derivative	The design of a processor. A description of one or more cores including internal memory and any number of buses.
Library	Collection of relocatable object files. Usually each object file in a library contains one symbol definition (for example, a function).
Logical address	An address as encoded in an instruction word, an address generated by a core (CPU).
LSL file	The set of linker script files that are passed to the linker.
MAU	Minimum Addressable Unit. For a given processor the number of bits between an address and the next address. This is not necessarily a byte or a word.
Object code	The binary machine language representation of the C/assembly source.
Physical address	An address generated by the memory system.
Processor	An instance of a derivative. Usually implemented as a (custom) chip, but can also be implemented in an FPGA, in which case the derivative can be designed by the developer.
Relocatable object file	Object code in which addresses are represented by symbols and thus relocatable.
Relocation	The process of assigning absolute addresses.

Term	Definition
Relocation information	Information about how the linker must modify the machine code instructions when it relocates addresses.
Section	A group of instructions and/or data objects that occupy a contiguous range of addresses.
Section attributes	Attributes that define how the section should be linked or located.
Target	The hardware board on which an application is executing. A board contains at least one processor. However, a complex target may contain multiple processors and external memory and may be shared between processors.
Unresolved reference	A reference to a symbol for which the linker did not find a definition yet.

5.1.1. Phase 1: Linking

The linker takes one or more relocatable object files and/or libraries as input. A relocatable object file, as generated by the assembler, contains the following information:

- *Header information:* Overall information about the file, such as the code size, name of the source file it was assembled from, and creation date.
- *Object code:* Binary code and data, divided into various named sections. Sections are contiguous chunks of code that have to be placed in specific parts of the memory. The program addresses start at zero for each section in the object file.
- *Symbols:* Some symbols are exported - defined within the file for use in other files. Other symbols are imported - used in the file but not defined (external symbols). Generally these symbols are names of routines or names of data objects.
- *Relocation information:* A list of places with symbolic references that the linker has to replace with actual addresses. When in the code an external symbol (a symbol defined in another file or in a library) is referenced, the assembler does not know the symbol's size and address. Instead, the assembler generates a call to a preliminary relocatable address (usually 0000), while stating the symbol name.
- *Debug information:* Other information about the object code that is used by a debugger. The assembler optionally generates this information and can consist of line numbers, C source code, local symbols and descriptions of data structures.

The linker resolves the external references between the supplied relocatable object files and/or libraries and combines the files into a single relocatable linker object file.

The linker starts its task by scanning all specified relocatable object files and libraries. If the linker encounters an unresolved symbol, it remembers its name and continues scanning. The symbol may be defined elsewhere in the same file, or in one of the other files or libraries that you specified to the linker. If the symbol is defined in a library, the linker extracts the object file with the symbol definition from the library. This way the linker collects all definitions and references of all of the symbols.

Next, the linker combines sections with the same section name and attributes into single sections. The linker also substitutes (external) symbol references by (relocatable) numerical addresses where possible.

TASKING VX-toolset for MCS User Guide

At the end of the linking phase, the linker either writes the results to a file (a single relocatable object file) or keeps the results in memory for further processing during the locating phase.

The resulting file of the linking phase is a single relocatable object file (`.out`). If this file contains unresolved references, you can link this file with other relocatable object files (`.o`) or libraries (`.a`) to resolve the remaining unresolved references.

With the linker command line option `--link-only`, you can tell the linker to only perform this linking phase and skip the locating phase. The linker complains if any unresolved references are left.

5.1.2. Phase 2: Locating

In the locating phase, the linker assigns absolute addresses to the object code, placing each section in a specific part of the target memory. The linker also replaces references to symbols by the actual address of those symbols. The resulting file is an absolute object file which you can actually load into a target memory. Optionally, when the resulting file should be loaded into a ROM device the linker creates a so-called copy table section which is used by the startup code to initialize the data and BSS sections.

Code modification

When the linker assigns absolute addresses to the object code, it needs to modify this code according to certain rules or *relocation expressions* to reflect the new addresses. These relocation expressions are stored in the relocatable object file. Consider the following snippet of x86 code that moves the contents of variable `a` to variable `b` via the `eax` register:

```
A1 3412 0000 mov a,%eax    (a defined at 0x1234, byte reversed)
A3 0000 0000 mov %eax,b    (b is imported so the instruction refers to
                           0x0000 since its location is unknown)
```

Now assume that the linker links this code so that the section in which `a` is located is relocated by `0x10000` bytes, and `b` turns out to be at `0x9A12`. The linker modifies the code to be:

```
A1 3412 0100 mov a,%eax    (0x10000 added to the address)
A3 129A 0000 mov %eax,b    (0x9A12 patched in for b)
```

These adjustments affect instructions, but keep in mind that any pointers in the data part of a relocatable object file have to be modified as well.

Output formats

The linker can produce its output in different file formats. The default ELF/DWARF format (`.elf`) contains an image of the executable code and data, and can contain additional debug information. The Intel-Hex format (`.hex`) and Motorola S-record format (`.sre`) only contain an image of the executable code and data. You can specify a format with the options `--output (-o)` and `--chip-output (-c)`.

Controlling the linker

Via a so-called *linker script file* you can gain complete control over the linker. The script language is called the *Linker Script Language* (LSL). Using LSL you can define:

- The memory installed in the embedded target system:

To assign locations to code and data sections, the linker must know what memory devices are actually installed in the embedded target system. For each physical memory device the linker must know its start-address, its size, and whether the memory is read-write accessible (RAM) or read-only accessible (ROM).

- How and where code and data should be placed in the physical memory:

Embedded systems can have complex memory systems. If for example on-chip and off-chip memory devices are available, the code and data located in internal memory is typically accessed faster and with dissipating less power. To improve the performance of an application, specific code and data sections should be located in on-chip memory. By writing your own LSL file, you gain full control over the locating process.

- The underlying hardware architecture of the target processor.

To perform its task the linker must have a model of the underlying hardware architecture of the processor you are using. For example the linker must know how to translate an address used within the object file (a logical address) into an offset in a particular memory device (a physical address). In most linkers this model is hard coded in the executable and can not be modified. For the TASKING linker this hardware model is described in the linker script file. This solution is chosen to support configurable cores that are used in system-on-chip designs.

When you want to write your own linker script file, you can use the standard linker script files with architecture descriptions delivered with the product.

See also [Section 5.7, Controlling the Linker with a Script](#).

5.2. Calling the Linker

In Eclipse you can set options specific for the linker. After you have built your project, the output files are available in a subdirectory of your project directory, depending on the active configuration you have set in the **C/C++ Build » Settings** page of the **Project » Properties for** dialog.

Building a project under Eclipse

You have several ways of building your project:

- Build Individual Project ()

To build individual projects incrementally, select **Project » Build project**.

- Rebuild Project () This builds every file in the project whether or not a file has been modified since the last build. A rebuild is a clean followed by a build.

1. Select **Project » Clean...**

2. Enable the option **Start a build immediately** and click **OK**.

- **Build Automatically.** This performs a build of all projects whenever any project file is saved, such as your makefile.

This way of building is not recommended, but to enable this feature select **Project » Build Automatically** and ensure there is a check mark beside the **Build Automatically** menu item. In order for this option to work, you must also enable option **Build on resource save (Auto build)** on the **Behavior** tab of the **C/C++ Build** page of the **Project » Properties for** dialog.

To access the linker options

1. From the **Project** menu, select **Properties for**
The Properties dialog appears.
2. In the left pane, expand **C/C++ Build** and select **Settings**.
In the right pane the Settings appear.
3. From the **Configuration** list, select a configuration or select [All configurations].
4. On the Tool Settings tab, select **Linker**.
5. Select the sub-entries and set the options in the various pages.

Note that when you click **Restore Defaults** to restore the default tool options, as a side effect the processor is also reset to its default value on the **Processor** page (**C/C++ Build » Processor**).

You can find a detailed description of all linker options in [Section 8.3, Linker Options](#).

Invocation syntax on the command line:

```
lmcs [ [option]... [file]... ]...
```

When you are linking multiple files, either relocatable object files (.o) or libraries (.a), it is important to specify the files in the right order. This is explained in [Section 5.3, Linking with Libraries](#).

You can find a detailed description of all linker options in [Section 8.3, Linker Options](#).

Example:

```
lmcs -dte39xb.lsl test.o
```

This links and locates the file `test.o` and generates the file `test.elf`.

5.3. Linking with Libraries

There are two kinds of libraries: system libraries and user libraries.

System library

System libraries are stored in the directory:

```
<installation path>\lib\mcs30\[be|le][\nmd] (MCS v3.0 libraries)
<installation path>\lib\mcs31\[be|le][\nmd] (MCS v3.1 libraries)
```

The libraries are available in big-endian (be) or little-endian (le) variants. For MCS cores without multiply and/or divide support, the libraries are present in the `nmd` directory.

An overview of the system libraries is given in the table in [Chapter 10, Libraries](#).

Sources for the libraries are present in the directories `lib\src`, `lib\src.*` in the form of an executable. If you run the executable it will extract the sources in the corresponding directory.

To link the default C (system) libraries

1. From the **Project** menu, select **Properties for**
The Properties dialog appears.
2. In the left pane, expand **C/C++ Build** and select **Settings**.
In the right pane the Settings appear.
3. On the Tool Settings tab, select **Linker » Libraries**.
4. Enable the option **Link default libraries**.

When you want to link system libraries from the command line, you must specify this with the option **--library (-l)**. For example, to specify the system library `libc.a`, type:

```
lmcs --library=c test.o
```

User library

You can create your own libraries. [Section 6.3, Archiver](#) describes how you can use the archiver to create your own library with object modules.

To link user libraries

1. From the **Project** menu, select **Properties for**
The Properties dialog appears.
2. In the left pane, expand **C/C++ Build** and select **Settings**.
In the right pane the Settings appear.
3. On the Tool Settings tab, select **Linker » Libraries**.
4. Add your libraries to the **Libraries** box.

TASKING VX-toolset for MCS User Guide

When you want to link user libraries from the command line, you must specify their filenames on the command line:

```
lmcs start.o mylib.a
```

If the library resides in a sub-directory, specify that directory with the library name:

```
lmcs start.o mylibs\mylib.a
```

If you do not specify a directory, the linker searches the library in the current directory only.

Library order

The order in which libraries appear on the command line is important. By default the linker processes object files and libraries in the order in which they appear at the command line. Therefore, when you use a weak symbol construction, like `printf`, in an object file or your own library, you must position this object/library before the C library.

With the option **--first-library-first** you can tell the linker to scan the libraries from left to right, and extract symbols from the first library where the linker finds it. This can be useful when you want to use newer versions of a library routine:

```
lmcs --first-library-first a.a test.o b.a
```

If the file `test.o` calls a function which is both present in `a.a` and `b.a`, normally the function in `b.a` would be extracted. With this option the linker first tries to extract the symbol from the first library `a.a`.

Note that routines in `b.a` that call other routines that are present in both `a.a` and `b.a` are now also resolved from `a.a`.

5.3.1. How the Linker Searches Libraries

System libraries

You can specify the location of system libraries in several ways. The linker searches the specified locations in the following order:

1. The linker first looks in the **Library search path** that are specified in the **Linker » Libraries** page in the **C/C++ Build » Settings » Tool Settings** tab of the Project Properties dialog (equivalent to the [option --library-directory \(-L\)](#)). If you specify the **-L** option without a pathname, the linker stops searching after this step.
2. When the linker did not find the library (because it is not in the specified library directory or because no directory is specified), it looks in the path(s) specified in the environment variable `LIBMCS`.
3. When the linker did not find the library, it tries the default `lib` directory relative to the installation directory (or a processor specific sub-directory).

User library

If you use your own library, the linker searches the library in the current directory only.

5.3.2. How the Linker Extracts Objects from Libraries

A library built with the TASKING archiver **armcs** always contains an index part at the beginning of the library. The linker scans this index while searching for unresolved externals. However, to keep the index as small as possible, only the defined symbols of the library members are recorded in this area.

When the linker finds a symbol that matches an unresolved external, the corresponding object file is extracted from the library and is processed. After processing the object file, the remaining library index is searched. If after a complete search of the library unresolved externals are introduced, the library index will be scanned again. After all files and libraries are processed, and there are still unresolved externals and you did not specify the linker option **--no-rescan**, all libraries are rescanned again. This way you do not have to worry about the library order on the command line and the order of the object files in the libraries. However, this rescanning does not work for 'weak symbols'. If you use a weak symbol construction, like `printf`, in an object file or your own library, you must position this object/library before the C library.

The option **--verbose (-v)** shows how libraries have been searched and which objects have been extracted.

Resolving symbols

If you are linking from libraries, only the objects that contain symbols to which you refer, are extracted from the library. This implies that if you invoke the linker like:

```
lmcs mylib.a
```

nothing is linked and no output file will be produced, because there are no unresolved symbols when the linker searches through `mylib.a`.

It is possible to force a symbol as external (unresolved symbol) with the option **--extern (-e)**:

```
lmcs --extern=main mylib.a
```

In this case the linker searches for the symbol `main` in the library and (if found) extracts the object that contains `main`.

If this module contains new unresolved symbols, the linker looks again in `mylib.a`. This process repeats until no new unresolved symbols are found.

5.4. Incremental Linking

With the TASKING linker it is possible to link incrementally. Incremental linking means that you link some, but not all `.o` modules to a relocatable object file `.out`. In this case the linker does not perform the locating phase. With the second invocation, you specify both new `.o` files as the `.out` file you had created with the first invocation.

Incremental linking is only possible on the command line.

```
lmcs --incremental test1.o -otest.out
lmcs test2.o test.out
```

This links the file `test1.o` and generates the file `test.out`. This file is used again and linked together with `test2.o` to create the file `test.elf` (the default name if no output filename is given in the default ELF/DWARF format).

With incremental linking it is normal to have unresolved references in the output file until all `.o` files are linked and the final `.out` or `.elf` file has been reached. The option **--incremental (-r)** for incremental linking also suppresses warnings and errors because of unresolved symbols.

5.5. Importing Binary Files

With the TASKING linker it is possible to add a binary file to your absolute output file. In an embedded application you usually do not have a file system where you can get your data from.

Add a data object in Eclipse

1. Select **Linker » Data Objects**.

The Data objects box shows the list of object files that are imported.

2. To add a data object, click on the **Add** button in the **Data objects** box.
3. Type or select a binary file (including its path).

On the command line you can add raw data to your application with the linker option **--import-object**.

This makes it possible for example to display images on a device or play audio. The linker puts the raw data from the binary file in a section. The section is aligned on a 4-byte boundary. The section name is derived from the filename, in which dots are replaced by an underscore. So, when importing a file called `my.mp3`, a section with the name `my_mp3` is created. In your application you can refer to the created section by using linker labels.

For example:

```
.extern __lc_ub_my_mp3; /* linker labels */
.extern __lc_ue_my_mp3;
```

If you want to use the export functionality of Eclipse, the binary file has to be part of your project.

5.6. Linker Optimizations

During the linking and locating phase, the linker looks for opportunities to optimize the object code. Both code size and execution speed can be optimized.

To enable or disable optimizations

1. From the **Project** menu, select **Properties for**

The Properties dialog appears.

2. In the left pane, expand **C/C++ Build** and select **Settings**.

In the right pane the Settings appear.

3. On the Tool Settings tab, select **Linker » Optimization**.
4. Enable one or more optimizations.

You can enable or disable the optimizations described below. The command line option for each optimization is given in brackets.

Delete unreferenced sections (option -Oc/-OC)

This optimization removes unreferenced sections from the resulting object file.

This optimization considers a section referenced if either of the following two conditions is true:

1. The section is protected from unreferenced section removal, which can be one of:
 - the section is assigned an absolute address, either in the object file or in LSL
 - the section is selected by exact name in LSL (no wildcard pattern) *
 - a symbol defined in the section is referenced in LSL
 - the section has the 'protected' section flag set, either in the object file or in LSL
2. The section is referenced via a relocation by another section that is considered referenced.

* If multiple sections of a specific name are created by using section renaming, all of these sections are protected against unreferenced section removal. With a selection using wildcards, matching sections are selected, but matching sections that are unreferenced may be removed. See [Selecting sections for a group](#) in [Section 13.8.2, Creating and Locating Groups of Sections](#).

First fit decreasing (option -OI/-OL)

When the physical memory is fragmented or when address spaces are nested it may be possible that a given application cannot be located although the size of the available physical memory is larger than the sum of the section sizes. Enable the first-fit-decreasing optimization when this occurs and re-link your application.

The linker's default behavior is to place sections in the order that is specified in the LSL file (that is, working from low to high memory addresses or vice versa). This also applies to sections within an unrestricted group. If a memory range is partially filled and a section must be located that is larger than the remainder of this range, then the section and all subsequent sections are placed in a next memory range. As a result of this gaps occur at the end of a memory range.

When the first-fit-decreasing optimization is enabled the linker will first place the largest sections in the smallest memory ranges that can contain the section. Small sections are located last and can likely fit in the remaining gaps.

Compress copy table (option -Ot/-OT)

The startup code initializes the application's data areas. The information about which memory addresses should be zeroed and which memory ranges should be copied from ROM to RAM is stored in the copy table.

When this optimization is enabled the linker will try to locate sections in such a way that the copy table is as small as possible thereby reducing the application's ROM image.

Note that this optimization only affects unrestricted sections that require an initialization action in the copy table. The affected sections get a clustered restriction. Unrestricted sections are sections that do not have their absolute location or their relative location to other sections restricted. See also [Define the mutual order of sections in an LSL group in Section 13.8.2, *Creating and Locating Groups of Sections*](#).

Delete duplicate code (option -Ox/-OX)

Delete duplicate constant data (option -Oy/-OY)

These two optimizations remove code and constant data that is defined more than once, from the resulting object file.

5.7. Controlling the Linker with a Script

With the options on the command line you can control the linker's behavior to a certain degree. From Eclipse it is also possible to determine where your sections will be located, how much memory is available, which sorts of memory are available, and so on. Eclipse passes these locating directions to the linker via a script file. If you want even more control over the locating process you can supply your own script.

The language for the script is called the *Linker Script Language*, or shortly LSL. You can specify the script file to the linker, which reads it and locates your application exactly as defined in the script. If you do not specify your own script file, the linker always reads a standard script file which is supplied with the toolset.

5.7.1. Purpose of the Linker Script Language

The Linker Script Language (LSL) serves three purposes:

1. It provides the linker with a definition of the target's core architecture. This definition is supplied with the toolset.
2. It provides the linker with a specification of the memory attached to the target processor.
3. It provides the linker with information on how your application should be located in memory. This gives you, for example, the possibility to create overlaying sections.

The linker accepts multiple LSL files. You can use the specifications of the core architectures that Altium has supplied in the `include.lsl` directory. Do not change these files.

If you use a different memory layout than described in the LSL file supplied for the target core, you must specify this in a separate LSL file and pass both the LSL file that describes the core architecture and your LSL file that contains the memory specification to the linker. Next you may want to specify how sections should be located and overlaid. You can do this in the same file or in another LSL file.

LSL has its own syntax. In addition, you can use the standard C preprocessor keywords, such as `#include` and `#define`, because the linker sends the script file first to the C preprocessor before it starts interpreting the script.

The complete LSL syntax is described in [Chapter 13, Linker Script Language \(LSL\)](#).

5.7.2. Eclipse and LSL

In Eclipse you can specify the size of the stack and heap; the physical memory attached to the processor; identify that particular address ranges are reserved; and specify which sections are located where in memory. Eclipse translates your input into an LSL file that is stored in the project directory under the name `project_name.lsl` and passes this file to the linker. If you want to learn more about LSL you can inspect the generated file `project_name.lsl`.

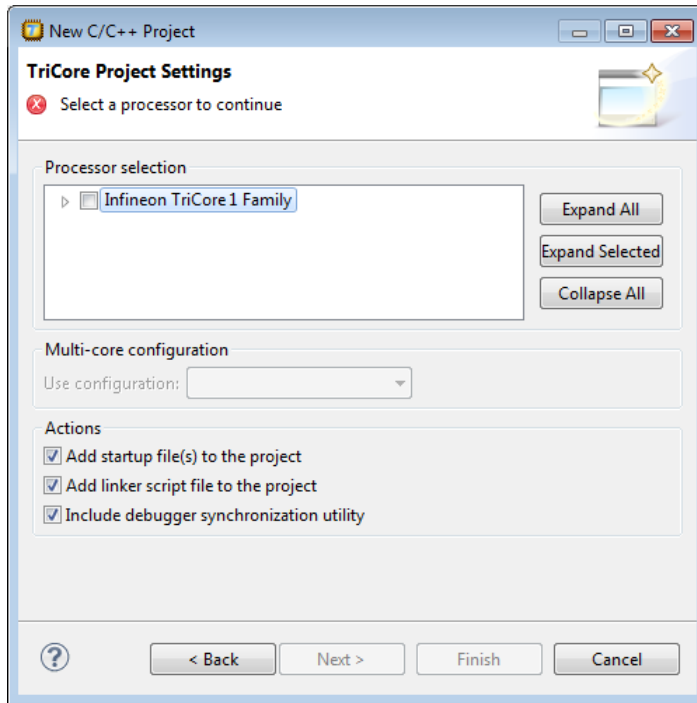

Because an MCS project is part of a TriCore project you only need to specify an LSL file to the TriCore project.

To add a generated Linker Script File to your project

1. From the **File** menu, select **File » New » TASKING TriCore C/C++ Project**.

The New C/C++ Project wizard appears.

2. Fill in the project settings in each dialog and click **Next >** until the following dialog appears.

3. Enable the option **Add linker script file to the project** and click **Finish**.

Eclipse creates your project and the file "project_name.lsl" in the project directory.

If you do not add the linker script file here, you can always add it later with **File » New » Linker Script File (LSL)**

To change the Linker Script File in Eclipse

There are two ways of changing the LSL file in Eclipse.

- You can change the LSL file directly in an editor.
 1. Double-click on the file *project_name.lsl*.

The project LSL file opens in the editor area.

```

myproject.lsl
// TASKING VX-toolset for TriCore
// Eclipse project linker script file
//
⊖ #if defined(__PROC_TC1796B__)
  #define __REDEFINE_ON_CHIP_ITEMS
  #include "tc1796b.lsl"
  processor spe
  {
    derivative = my_tc1796b;
  }
  derivative my_tc1796b extends tc1796b
  {
    memory pflash (tag="on-chip")
    {
      mau = 8;
      type = rom;
      size = 2M;
      priority = 2;
      map cached(dest=bus:tc:fpi_bus, dest_offset=0x80000000, size=
      map not_cached(dest=bus:tc:fpi_bus, dest_offset=0xa0000000, s
    }
  }

```

2. You can edit the LSL file directly in the `project_name.lsl` editor.
*A * appears in front of the name of the LSL file to indicate that the file has changes.*
 3. Click  or select **File » Save** to save the changes.
- You can also make changes to the property pages Memory (Memory/Reserved/MCS Macros) and Stack/Heap.
 1. From the **Project** menu, select **Properties for**
The Properties dialog appears.
 2. In the left pane, expand **C/C++ Build** and select **Memory** or **Stack/Heap**.
In the right pane the corresponding property page appears.
 3. Make changes to memory and/or stack/heap and click **OK**.
The project LSL file is updated automatically according to the changes you make in the pages.

You can quickly navigate through the LSL file by using the Outline view (**Window » Show View » Outline**).

5.7.3. Preprocessor Macros in the Linker Script Files

The linker script files contain several predefined preprocessor macros. If for some reason you need to change a default value, you can use Eclipse or the linker option `--define` to define a new value, or add this option via the control program to the linker.

For example, to set the stack size for channel 0 of MCS core 00 from the command line to 48, enter:

```
ccmcs -Wl--define=GTM_MCS00_STACK_0=48 test.o
```

With option `-WI` the control program passes the macro definition to the linker.

The following macros are available in the linker script files.

Macro	Description
GTM_CPU_ENDIANNES	Identifies the endianness (big or little) of the main processing cores of the CPU based on the option <code>--endianness</code> .
GTM_MCFG_CTRL	Identifies the value of the MCFG_CTRL register that determines the GTM memory configuration. The default is 0x00000000, which is no swap and no borrow.
GTM_MCS_COPYTABLE_SPACE	Identifies the LSL address space (on the CPU) that holds the copy table used to initialize GTM MCS memory.
GTM_MCScore_HEAP	Identifies the size of the heap for the specified MCS core. The default is 256 octets.
GTM_MCScore_MAIN_CHANNEL	It is possible to execute the <code>main()</code> function on an arbitrary channel for specified MCS core. You can set this macro to the channel number in the range [0 .. 7]. If this macro is not defined, the <code>main()</code> function will be executed on channel 0.
GTM_MCS_NO_START_ADDRESS	If defined, no start address (<code>__START</code>) will specified in the LSL file.
GTM_MCS_NO_VECTOR_TABLE	If defined, no vector table will specified in the LSL file.
GTM_MCS_RAM0_SIZE	Identifies the size of a large MCS memory block in octets (default: 0x1000).
GTM_MCS_STACKS_BALLOONING	By default all MCS stacks have a fixed size. When this macro is defined, stacks will be "ballooning". This means that after locating all sections, the largest remaining gap in the space is used completely for the stack.
GTM_MCScore_STACK_channel	Identifies the size of the stack for the specified channel of the MCS core. <i>channel</i> is a number in the range [0 .. 7]. By default, all MCS stacks are 64 octets.
GTM_MCScore_STACK_channel_ENTRY_POINTS	Specifies the entry points for stack estimation of the stack for the specified <i>channel</i> of the MCS core. By default the macro for the main channel is set to " <code>__START</code> ".
MCS_RAM1_EN_ADDR_MSB	If defined as 1, the second memory block of each MCS is half the size of the first memory block. If this macro is undefined, the second memory block of each MCS is the same size as the first memory block.

Macro	Description
MCS00_0RAM .. MCS07_0RAM	Identifies the offset of the memory for core MCS00 .. MCS07 from the GTM base address.
GTM_REDEFINE_ON_CHIP_ITEMS	If defined as 1, no memories are defined in the GTM.

5.7.4. Structure of a Linker Script File

A script file consists of several definitions. The definitions can appear in any order.

The architecture definition (required)

In essence an *architecture definition* describes how the linker should convert logical addresses into physical addresses for a given type of core. If the core supports multiple address spaces, then for each space the linker must know how to perform this conversion. In this context a physical address is an offset on a given internal or external bus. Additionally the architecture definition contains information about items such as the stack.

This specification is normally written by Altium. Altium supplies LSL files in the `include.lsl` directory.

The architecture definition of the LSL file should not be changed by you unless you also modify the core's hardware architecture. If the LSL file describes a multi-core system an architecture definition must be available for each different type of core.

The linker uses the architecture name in the LSL file to identify the target. For example, the default library search path can be different for each core architecture.

The derivative definition

The *derivative definition* describes the configuration of the internal (on-chip) bus and memory system. Basically it tells the linker how to convert offsets on the buses specified in the architecture definition into offsets in internal memory. Microcontrollers and DSPs often have internal memory and I/O sub-systems apart from one or more cores. The design of such a chip is called a *derivative*.

When you want to use multiple cores of the same type, you must instantiate the cores in a derivative definition, since the linker automatically instantiates only a single core for an unused architecture.

Altium supplies LSL files for each derivative (`derivative.lsl`). When you use a derivative that is not (yet) supported by the TASKING tools, you may have to write a derivative definition.

The processor definition

The *processor definition* describes an instance of a derivative. A processor definition is only needed in a multi-processor embedded system. It allows you to define multiple processors of the same type.

If for a derivative 'A' no processor is defined in the LSL file, the linker automatically creates a processor named 'A' of derivative 'A'. This is why for single-processor applications it is enough to specify the derivative in the LSL file.

The memory and bus definitions (optional)

Memory and bus definitions are used within the context of a derivative definition to specify internal memory and on-chip buses. In the context of a board specification the memory and bus definitions are used to define external (off-chip) memory and buses. Given the above definitions the linker can convert a logical address into an offset into an on-chip or off-chip memory device.

The board specification

The processor definition and memory and bus definitions together form a board specification. LSL provides language constructs to easily describe single-core and heterogeneous or homogeneous multi-core systems. The board specification describes all characteristics of your target board's system buses, memory devices, I/O sub-systems, and cores that are of interest to the linker. Based on the information provided in the board specification the linker can for each core:

- convert a logical address to an offset within a memory device
- locate sections in physical memory
- maintain an overall view of the used and free physical memory within the whole system while locating

The section layout definition (optional)

The optional section layout definition enables you to exactly control where input sections are located. Features are provided such as: the ability to place sections at a given address, to place sections in a given order, and to overlay code and/or data sections.

Example: Skeleton of a Linker Script File

A linker script file that defines a derivative "X" based on the TC1V1.6.2 and MCS architecture, its external memory and how sections are located in memory, may have the following skeleton:

```
architecture TC1V1.6.2
{
    // Specification of the TC1V1.6.2 core architecture.
    // Written by Altium.
}

architecture MCS
{
    // Specification of the MCS core architecture.
    // Written by Altium.
}

derivative X // derivative name is arbitrary
{
    // Specification of the derivative.
    // Written by Altium.
    core tc0 // always specify the core(s)
    {
        architecture = TC1V1.6.2;
```

```
    // ...
}

core tc1          // always specify the core(s)
{
    architecture = TC1V1.6.2;
    // ...
}

core tc2          // always specify the core(s)
{
    architecture = TC1V1.6.2;
    // ...
}

core tc3          // always specify the core(s)
{
    architecture = TC1V1.6.2;
    // ...
}

core tc4          // always specify the core(s)
{
    architecture = TC1V1.6.2;
    // ...
}

core tc5          // always specify the core(s)
{
    architecture = TC1V1.6.2;
    // ...
}

core mcs00        // always specify the core(s)
{
    architecture = MCS;
    // ...
}

core mcs01        // always specify the core(s)
{
    architecture = MCS;
    // ...
}

core vtc          // virtual core
{
    architecture = TC1V1.6.2;
    import tc0;
    import tc1;
}
```

TASKING VX-toolset for MCS User Guide

```
import tc2;
import tc3;
import tc4;
import tc5;
}

bus sri          // internal bus
{
    // maps to bus "fpi_bus" in real "tc0", "tc1", ... cores
    // and virtual core "vtc"
}

// internal memory
}

processor mpe          // multi-core processor name
{
    derivative = X;
}

memory ext_name
{
    // external memory definition
}

section_layout :vtc:linear // section layout
{
    // section placement statements

    // sections are located in address space 'linear'
    // of virtual core 'vtc'
}
```

See for example the file `tc39xb.lsl` and `gtm31_10.lsl` in the directory `include.lsl` for an actual implementation.

Overview of LSL files delivered by Altium

Altium supplies the following LSL files in the directory `include.lsl`.

LSL file	Description
<code>tc_arch.lsl</code>	Defines the base architecture (TC) for all generic TriCore cores. It includes the files <code>inttab.lsl</code> and <code>traptab.lsl</code> .
<code>tc_mc_arch.lsl</code>	Defines the base architecture (TC) for all multi-core TriCore cores.
<code>mcs_arch.lsl</code>	Defines the base architectures (MCS, MCS2.0, MCS3.0, MCS3.1) for all MCS cores.
<code>inttab.lsl</code>	Defines the interrupt vector table. It is included in the file <code>tc_arch.lsl</code> .

LSL file	Description
inttab{0 1 2}.lsl	Defines a core specific interrupt vector table. It is included in derivative LSL files that have multi-core support.
traptab.lsl	Defines the trap vector table. It is included in the file <code>tc_arch.lsl</code> .
traptab{0 1 2}.lsl	Defines a core specific trap vector table. It is included in derivative LSL files that have multi-core support.
tclv1_3.lsl tclv1_3_1.lsl tclv1_6.lsl tclv1_6_x.lsl tclv1_6_2.lsl	Extends the base architecture for cores TC1V1.3, TC1V1.3.1, TC1V1.6, TC1V1.6.X or TC1V1.6.2. It includes the file <code>tc_arch.lsl</code> or <code>tc_mc_arch.lsl</code> .
derivative.lsl	Defines the derivative and defines a single processor (<code>spe</code>) or a multi-core processor (<code>mpe</code>). Contains a memory definition and section layout. It includes one of the files <code>tcversion.lsl</code> . The selection of the derivative is based on your CPU selection (control program option <code>--cpu</code>).
userdef13.lsl userdef131.lsl userdef16.lsl userdef16x.lsl userdef162.lsl	Defines a user defined derivative for cores TC1V1.3, TC1V1.3.1, TC1V1.6, TC1V1.6.X or TC1V1.6.2 and defines a single processor for TC1V1.3, TC1V1.3.1 and TC1V1.6, and a multi-core processor for TC1V1.6.X and TC1V1.6.2
template.lsl	This file is used by Eclipse as a template for the project LSL file. It includes the file <code>derivative.lsl</code> based on your CPU selection. The CPU is specified by the <code>__CPU__</code> macro.
default.lsl	Contains a default memory definition and section layout based on the tc1796b derivative. This file is used on a command line invocation of the tools, when no CPU is selected (no option <code>--cpu</code>). It includes the file <code>extmem.lsl</code> .
extmem.lsl	Template file with a specification of the external memory attached to the target processor.

When you select to add a linker script file when you create a project in Eclipse, Eclipse makes a copy of the file `template.lsl` and names it "`project_name.lsl`". On the command line, the linker uses the file `default.lsl`, unless you specify another file with the linker option `--lsl-file (-d)`.

5.7.5. The Architecture Definition

Although you will probably not need to write an architecture definition (unless you are building your own processor core) it helps to understand the Linker Script Language and how the definitions are interrelated.

Within an *architecture definition* the characteristics of a target processor core that are important for the linking process are defined. These include:

- space definitions: the logical address spaces and their properties
- bus definitions: the I/O buses of the core architecture
- mappings: the address translations between logical address spaces, the connections between logical address spaces and buses and the address translations between buses

Address spaces

A logical address space is a memory range for which the core has a separate way to encode an address into instructions. Most microcontrollers and DSPs support multiple address spaces. For example, separate spaces for code and data. Normally, the size of an address space is 2^N , with N the number of bits used to encode the addresses.

The relation of an address space with another address space can be one of the following:

- one space is a subset of the other. These are often used for "small" absolute or relative addressing.
- the addresses in the two address spaces represent different locations so they do not overlap. This means the core must have separate sets of address lines for the address spaces. For example, in Harvard architectures we can identify at least a code and a data memory space.

Address spaces (even nested) can have different minimal addressable units (MAU), alignment restrictions, and page sizes. All address spaces have a number that identifies the logical space (id).

The following table lists the different address spaces for the architecture TC as defined in `tc_mc_arch.lsl`.

Space	Id	MAU	Description	ELF sections
linear	1	1	Linear address space.	.text, .bss, .data, .rodata, table, istack, ustack
abs24	2	8	Absolute 24-bit addressable space	
abs18	3	8	Absolute 18-bit addressable space.	.zdata, .zbss
csa	4	8	Context Save Area	csa.*

The MCS, which is part of TriCore v1.6.x and v1.6.2 derivatives, such as TC39xB, has one address space for architecture MCS as defined in `mcs_arch.lsl`.

Space	Id	MAU	Description	ELF sections
mcs	1	8	MCS address space	.mcstext, .mcsdata

The TriCore architecture in LSL notation

The best way to write the architecture definition, is to start with a drawing. The following figure shows a part of the TriCore architecture TC as defined in `tc_mc_arch.lsl`:

The figure shows two address spaces called `linear` and `abs18`. The address space `abs18` is a subset of the address space `linear`. All address spaces have attributes like a number that identifies the logical

space (id), a MAU and an alignment. In LSL notation the definition of these address spaces looks as follows:

```
space linear
{
    id = 1;
    mau = 8;

    map (src_offset=0x00000000, dest_offset=0x00000000,
        size=4G, dest=bus:fpi_bus);
    //...
}

space abs18
{
    id = 3;
    mau = 8;

    map (src_offset=0x00000000, dest_offset=0x00000000,
        size=16k, dest=space:linear);
    map (src_offset=0x10000000, dest_offset=0x10000000,
        size=16k, dest=space:linear);
    map (src_offset=0x20000000, dest_offset=0x20000000,
        size=16k, dest=space:linear);
    //...
}
```

The keyword `map` corresponds with the arrows in the drawing. You can map:

- address space => address space
- address space => bus
- memory => bus (not shown in the drawing)
- bus => bus (not shown in the drawing)

Next the internal bus, named `fpi_bus` must be defined in LSL:

```
bus fpi_bus
{
    mau = 8;
    width = 32; // there are 32 data lines on the bus
}
```

This completes the LSL code in the architecture definition. Note that all code above goes into the architecture definition, thus between:

```
architecture TC1V1.6.2
{
    // All code above goes here.
}
```

5.7.6. The Derivative Definition

Although you will probably not need to write a derivative definition (unless you are using multiple cores that both access the same memory device) it helps to understand the Linker Script Language and how the definitions are interrelated.

A *derivative* is the design of a processor, as implemented on a chip (or FPGA). It comprises one or more cores and on-chip memory. The derivative definition includes:

- core definition: an instance of a core architecture
- bus definition: the I/O buses of the core architecture
- memory definitions: internal (or on-chip) memory

Core

Each derivative must have at least one core and each core must have a specification of its core architecture. This core architecture must be defined somewhere in the LSL file(s).

```
core mcs00
{
    architecture = MCS3.1;
    copytable_space = vtc:linear; // use copytable from core vtc
}
```

In a multi-core environment you can combine multiple cores with the same architecture into a single link task. This is done by importing one or more cores into a root core. The imported cores share a single symbol namespace. The address spaces in each imported core must have a unique ID in the link task. For each imported core is specified that the space IDs of the imported core start at a specific offset. If writable sections for a core must be initialized by using the copy table of a different core, this is specified by a `copytable_space`. The following example is part of `tc39xb.lsl` delivered with the product.

```
core tc0 // core 0
{
    architecture = TC1V1.6.2;
    space_id_offset = 100; // add 100 to all space IDs in
                          // the architecture definition
    copytable_space = vtc:linear; // use copytable from core vtc
}
core tc1 // core 1
{
    architecture = TC1V1.6.2;
    space_id_offset = 200; // add 200 to all space IDs in
                          // the architecture definition
    copytable_space = vtc:linear; // use copytable from core vtc
}
core tc2 // core 2
{
    architecture = TC1V1.6.2;
```

```

    space_id_offset = 300; // add 300 to all space IDs in
                          // the architecture definition
    copytable_space = vtc:linear; // use copytable from core vtc
}

core tc3 // core 3
{
    architecture = TC1V1.6.2;
    space_id_offset = 400; // add 400 to all space IDs in
                          // the architecture definition
    copytable_space = vtc:linear; // use copytable from core vtc
}

core tc4 // core 4
{
    architecture = TC1V1.6.2;
    space_id_offset = 500; // add 500 to all space IDs in
                          // the architecture definition
    copytable_space = vtc:linear; // use copytable from core vtc
}

core tc5 // core 5
{
    architecture = TC1V1.6.2;
    space_id_offset = 600; // add 600 to all space IDs in
                          // the architecture definition
    copytable_space = vtc:linear; // use copytable from core vtc
}

core vtc
{
    architecture = TC1V1.6.2;
    import tc0; // add all address spaces of tc0 for linking
    import tc1; // add all address spaces of tc1 for linking
    import tc2; // add all address spaces of tc2 for linking
    import tc3; // add all address spaces of tc3 for linking
    import tc4; // add all address spaces of tc4 for linking
    import tc5; // add all address spaces of tc5 for linking
}

```

Bus

Each derivative can contain a bus definition for connecting external memory. In this example, the bus `fpi_bus` maps to the bus `fpi_bus` defined in the architecture definition of core `tc`:

```

bus fpi_bus
{
    mau = 8;
    width = 32;
}

```

```
    map (dest=bus:tc:fpi_bus, dest_offset=0, size=4G);  
}
```

Memory

External memory is usually described in a separate memory definition, but you can specify on-chip memory for a derivative. For example:

```
memory dspr0  
{  
    mau = 8;  
    size = 128k;  
    type = ram;  
    map (dest=bus:tc0:fpi_bus, dest_offset=0xd0000000,  
        size=128k, priority=8);  
    map (dest=bus:sri, dest_offset=0xd8000000, size=128k);  
}
```

This completes the LSL code in the derivative definition. Note that all code above goes into the derivative definition, thus between:

```
derivative X    // name of derivative  
{  
    // All code above goes here  
}
```

5.7.7. The Processor Definition

The processor definition is only needed when you write an LSL file for a multi-processor embedded system. The processor definition explicitly instantiates a derivative, allowing multiple processors of the same type.

```
processor name  
{  
    derivative = derivative_name;  
}
```

If no processor definition is available that instantiates a derivative, a processor is created with the same name as the derivative.

Altium defines a “multi processor environment” (mpe) in each *derivative.lsl* file. For example:

```
processor mpe  
{  
    derivative = tc39xb;  
}
```

5.7.8. The Memory Definition

Once the core architecture is defined in LSL, you may want to extend the processor with external (or off-chip) memory. You need to specify the location and size of the physical external memory devices in the target system.

The principle is the same as defining the core's architecture but now you need to fill the memory definition:

```
memory name
{
    // memory definitions
}
```

Suppose your embedded system has 16 kB of external ROM, named `code_rom` and 2 kB of external NVRAM, named `my_nvram`. Both memories are connected to the bus `fpi_bus`. In LSL this looks like:

```
memory code_rom
{
    mau = 8;
    size = 16k;
    type = rom;
    map( dest=bus:mpe:fpi_bus, dest_offset=0xa0000000, size=16k );
}

memory my_nvram
{
    mau = 8;
    size = 2k;
    type = nvram;
    map( dest=bus:mpe:fpi_bus, dest_offset=0xc0000000, size=2k );
}
```

If you use a different memory layout than described in the LSL file supplied for the target core, you can specify this in Eclipse or you can specify this in a separate LSL file and pass both the LSL file that describes the core architecture and your LSL file that contains the memory specification to the linker.

To add memory using Eclipse

1. From the **Project** menu, select **Properties for**

The Properties dialog appears.

TASKING VX-toolset for MCS User Guide

2. In the left pane, expand **C/C++ Build** and select **Memory**.

In the right pane the Memory page appears.

3. Open the **Memory** tab and click on the **Add...** button.

The Add new memory dialog appears.

4. Enter the memory name, type and size.

5. Click on the **Add...** button.

The Add new mapping dialog appears.

6. You have to specify at least one mapping. Enter the mapping name (optional), address, size and destination and click **OK**.

The new mapping is added to the list of mappings.

7. Click **OK**.

The new memory is added to the list of memories (user memory).

8. Click **OK** to close the Properties dialog.

The updated settings are stored in the project LSL file.

If you make changes to the on-chip memory as defined in the architecture LSL file, the memory is copied to your project LSL file and the line `#define __REDEFINE_ON_CHIP_ITEMS` is added. If you remove all the on-chip memory from your project LSL file, also make sure you remove this define.

5.7.9. The Section Layout Definition: Locating Sections

Once you have defined the internal core architecture and optional memory, you can actually define where your application must be located in the physical memory.

Sections have a name, an indication (section type) in which address space it should be located and attributes like writable or read-only.

In the section layout definition you can exactly define how input sections are placed in address spaces, relative to each other, and what their absolute run-time and load-time addresses will be.

Section placement

Suppose we want to save sections in non-volatile (battery back-upped) memory. This is the memory `my_nvsram` from the example in [Section 5.7.8, The Memory Definition](#).

To control the locating of sections, you need to write one or more section definitions in the LSL file. At least one for each address space where you want to change the default behavior of the linker. In our example, we need to locate sections in the address space `mcs`:

```
section_layout :mcs00:mcs
{
```

```

    // Section placement statements
}

section_layout :vtc:linear
{
    // Section placement statements
}

```

To locate sections, you must create a group in which you select sections from your program. For our example, we need to define one group, which contains the section `.mcsdata.non_volatile`. All other sections are located using the defaults specified in the architecture definition. Section `.mcsdata.non_volatile` should be placed in non-volatile ram. To achieve this, the run address refers to our non-volatile memory called `my_nvram`.

```

group ( run_addr = mem:my_nvram )
{
    select ".mcsdata.non_volatile";
}

```

This completes the LSL file for the sample architecture and sample program. You can now invoke the linker with this file and the sample program to obtain an application that works for this architecture.

For a complete description of the Linker Script Language, refer to [Chapter 13, Linker Script Language \(LSL\)](#).

5.7.9.1. Locating Code and Data Sections in Separate Pages

When code and data are in the same memory page, this will have a negative effect on the run-time speed. To have the best performance, code must end up in `mp0` and data in `mp1`.

The following example shows how to do this in LSL. Note that for "code in `mp0`, data in `mp0`", the directions need to be reversed. Only a `section_layout` with `high_to_low` is needed since `low_to_high` is the default.

```

section_layout :mcs00:mcs (direction=high_to_low)
{
    group (contiguous)
    {
        select ".mcstext";
        select ".mcstext.*";
    }
}

section_layout :mcs00:mcs (direction=low_to_high)
{
    group (contiguous)
    {
        select ".mcsdata";
        select ".mcsdata.*";
    }
}

```

5.8. Linker Labels

The linker creates labels that you can use to refer to from within the application software. Some of these labels are real labels at the beginning or the end of a section. Other labels have a second function, these labels are used to address generated data in the locating phase. The data is only generated if the label is used.

Linker labels are labels starting with `_lc_`. The linker assigns addresses to the following labels when they are referenced:

Label	Description
<code>_lc_ub_name</code> <code>_lc_b_name</code>	Begin of section <i>name</i> . Also used to mark the begin of the stack or heap or copy table.
<code>_lc_ue_name</code> <code>_lc_e_name</code>	End of section <i>name</i> . Also used to mark the end of the stack or heap.
<code>_lc_gb_name</code>	Begin of group <i>name</i> . This label appears in the output file even if no reference to the label exists in the input file.
<code>_lc_ge_name</code>	End of group <i>name</i> . This label appears in the output file even if no reference to the label exists in the input file.

The linker only allocates space for the stack and/or heap when a reference to either of the section labels exists in one of the input object files.

If there is no LSL file in your project, select **File » New » Linker Script File (LSL)**, add the lines that define the symbol. Add the LSL file to the linker options (**Tool Options » Linker » Script File » Linker script file (.isl)**).

When the MCS linked project (`.out`) is linked with a TriCore project, then the TriCore LSL file also needs this addition.

5.9. Generating a Map File

The map file is an additional output file that contains information about the location of sections and symbols. You can customize the type of information that should be included in the map file.

To generate a map file

- From the **Project** menu, select **Properties for**
The Properties dialog appears.
- In the left pane, expand **C/C++ Build** and select **Settings**.
In the right pane the Settings appear.
- On the Tool Settings tab, select **Linker » Map File**.

4. Enable the option **Generate XML map file format (.mapxml) for map file viewer**.
5. (Optional) Enable the option **Generate map file (.map)**.
6. (Optional) Enable the options to include that information in the map file.

Example on the command line

The following command generates the map file `test.map`:

```
lmcs --map-file test.o
```

With this command the map file `test.map` is created.

See [Section 11.2, Linker Map File Format](#), for an explanation of the format of the map file.

5.10. Linker Error Messages

The linker reports the following types of error messages in the Problems view of Eclipse.

F (Fatal errors)

After a fatal error the linker immediately aborts the link/locate process.

E (Errors)

Errors are reported, but the linker continues linking and locating. No output files are produced unless you have set the linker option **--keep-output-files**.

W (Warnings)

Warning messages do not result into an erroneous output file. They are meant to draw your attention to assumptions of the linker for a situation which may not be correct. You can control warnings in the **C/C++ Build » Settings » Tool Settings » Linker » Diagnostics** page of the **Project » Properties for** menu (linker option **--no-warnings**).

I (Information)

Verbose information messages do not indicate an error but tell something about a process or the state of the linker. To see verbose information, use the linker option **--verbose**.

S (System errors)

System errors occur when internal consistency checks fail and should never occur. When you still receive the system error message

```
S6##: message
```

please report the error number and as many details as possible about the context in which the error occurred.

Display detailed information on diagnostics

1. From the **Window** menu, select **Show View » Other » TASKING » Problems**.

The Problems view is added to the current perspective.

2. In the Problems view right-click on a message.

A popup menu appears.

3. Select **Detailed Diagnostics Info**.

A dialog box appears with additional information.

On the command line you can use the linker option **--diag** to see an explanation of a diagnostic message:

```
lmcs --diag=[format:]{all | number,...}
```

Chapter 6. Using the Utilities

The TASKING VX-toolset for MCS comes with a number of utilities:

- ccmcs** A control program. The control program invokes all tools in the toolset and lets you quickly generate an absolute object file from assembly source input files. Eclipse uses the control program to call the assembler and linker.
- amk** A make utility to maintain, update, and reconstruct groups of programs. The make utility looks whether files are out of date, rebuilds them and determines which other files as a consequence also need to be rebuilt. It supports parallelism which utilizes the multiple cores found on modern host hardware.
- armcs** An archiver. With this utility you create and maintain library files with relocatable object modules (.o) generated by the assembler.
- hldumpmcs** A high level language (HLL) object dumper. With this utility you can dump information about an absolute object file (.elf). Key features are a disassembler with HLL source intermixing and HLL symbol display and a HLL symbol listing of static and global symbols.
- cnvba2ta.pl** A Perl script to convert Bosch MCS assembly to TASKING assembly for MCS.

6.1. Control Program

The control program is a tool that invokes all tools in the toolset for you. It provides a quick and easy way to generate the final absolute object file out of your C sources without the need to invoke the compiler, assembler and linker manually.

Eclipse uses the control program to call the C compiler, assembler and linker, but you can call the control program from the command line. The invocation syntax is:

```
ccmcs [ [option]... [file]... ]...
```

Recognized input files

- Files with a .c suffix are interpreted as C source programs and are passed to the compiler.
- Files with a .asm suffix are interpreted as hand-written assembly source files which have to be passed to the assembler.
- Files with a .src suffix are interpreted as compiled assembly source files. They are directly passed to the assembler.
- Files with a .a suffix are interpreted as library files and are passed to the linker.
- Files with a .o suffix are interpreted as object files and are passed to the linker.
- Files with a .out suffix are interpreted as linked object files and are passed to the locating phase of the linker. The linker accepts only one .out file in the invocation.
- Files with a .lsl suffix are interpreted as linker script files and are passed to the linker.

Options

The control program accepts several command line options. If you specify an unknown option to the control program, the control program looks if it is an option for a specific tool. If so, it passes the option directly to the tool. However, it is recommended to use the control program options **--pass-*** (**-Wc**, **-Wa**, **-WI**) to pass arguments directly to tools.

For a complete list and description of all control program options, see [Section 8.4, Control Program Options](#).

Example with verbose output

```
ccmcs --verbose --cpu=tc39xb test.c
```

The control program calls all tools in the toolset and generates the absolute object file `test.elf`. With option **--verbose** (**-v**) you can see how the control program calls the tools:

```
+ "path\cmcs" --instruction-set=dm -D__CPU__=tc39xb  
  -D__CPU_TC39XB__ --core=mcs3.1 --fp-model=cFlnrTz -o cc5966a.src test.c  
+ "path\asmcs" --instruction-set=dm -D__CPU__=tc39xb  
  -D__CPU_TC39XB__ --core=mcs3.1 --endianness=little -o cc5966b.o cc5966a.src  
+ "path\lmcs" -o test.out -d tc39xb.lsl --core=mcs00  
  --endianness=little -D__CPU__=tc39xb -D__PROC_TC39XB__  
  --link-only -D__LINKONLY__ --map-file cc5966b.o  
  "-Lpath\lib\mcs31\le" -lc -lfp -lrt
```

The control program produces unique filenames for intermediate steps in the build process (such as `cc5966a.src` and `cc5966b.o` in the example above) which are removed afterwards, unless you specify command line option **--keep-temporary-files** (**-t**).

Example with argument passing to a tool

```
ccmcs --pass-c=-Oc test.c
```

The option **-Oc** is directly passed to the compiler.

6.2. Make Utility `amk`

amk is a make utility that you can use to maintain, update, and reconstruct groups of programs. **amk** features parallelism which utilizes the multiple cores found on modern host hardware, hardening for path names with embedded white space and it has an (internal) interface to provide progress information for updating a progress bar. It does not use an external command shell (`/bin/sh`, `cmd.exe`) but executes commands directly.

The primary purpose of any make utility is to speed up the edit-build-test cycle. To avoid having to build everything from scratch even when only one source file changes, it is necessary to describe dependencies between source files and output files and the commands needed for updating the output files. This is done in a so called "makefile".

6.2.1. Makefile Rules

A makefile dependency rule is a single line of the form:

```
[target ...] : [prerequisite ...]
```

where *target* and *prerequisite* are path names to files. Example:

```
test.o : test.c
```

This states that target `test.o` depends on prerequisite `test.c`. So, whenever the latter is modified the first must be updated. Dependencies accumulate: prerequisites and targets can be mentioned in multiple dependency rules (circular dependencies are not allowed however). The command(s) for updating a target when any of its prerequisites have been modified must be specified with leading white space after any of the dependency rule(s) for the target in question. Example:

```
test.o :
    ccmcs test.c    # leading white space
```

Command rules may contain dependencies too. Combining the above for example yields:

```
test.o : test.c
    ccmcs test.c
```

White space around the colon is not required. When a path name contains special characters such as `'`, `#` (start of comment), `=` (macro assignment) or any white space, then the path name must be enclosed in single or double quotes. Quoted strings can contain anything except the quote character itself and a newline. Two strings without white space in between are interpreted as one, so it is possible to embed single and double quotes themselves by switching the quote character.

When a target does not exist, its modification time is assumed to be very old. So, **amk** will try to make it. When a prerequisite does not exist possibly after having tried to make it, it is assumed to be very new. So, the update commands for the current target will be executed in that case. **amk** will only try to make targets which are specified on the command line. The default target is the first target in the makefile which does not start with a dot.

Static pattern rules

Static pattern rules are rules which specify multiple targets and construct the prerequisite names for each target based on the target name.

```
[target ...] : target-pattern : [prerequisite-patterns ...]
```

The *target* specifies the targets the rules applies to. The *target-pattern* and *prerequisite-patterns* specify how to compute the prerequisites of each target. Each target is matched against the *target-pattern* to extract a part of the target name, called the *stem*. This stem is substituted into each of the *prerequisite-patterns* to make the prerequisite names (one from each *prerequisite-pattern*).

Each pattern normally contains the character '%' just once. When the *target-pattern* matches a target, the '%' can match any part of the target name; this part is called the *stem*. The rest of the pattern must match exactly. For example, the target `foo.o` matches the pattern `%.o`, with `'foo'` as the stem. The targets `foo.c` and `foo.elf` do not match that pattern.

The prerequisite names for each target are made by substituting the stem for the '%' in each prerequisite pattern.

Example:

```
objects = test.o filter.o

all: $(objects)

$(objects): %.o: %.c
    ccmcs -c $< -o $@
    echo the stem is $*
```

Here '\$<' is the automatic variable that holds the name of the prerequisite, '\$@' is the automatic variable that holds the name of the target and '\$*' is the stem that matches the pattern. Internally this translates to the following two rules:

```
test.o: test.c
    ccmcs -c test.c -o test.o
    echo the stem is test

filter.o: filter.c
    ccmcs -c filter.c -o filter.o
    echo the stem is filter
```

Each target specified must match the target pattern; a warning is issued for each target that does not.

Special targets

There are a number of special targets. Their names begin with a period.

Target	Description
.DONE	When the make utility has finished building the specified targets, it continues with the rules following this target.

Target	Description
<code>.INIT</code>	The rules following this target are executed before any other targets are built.
<code>.PHONY</code>	<p>The prerequisites of this target are considered to be phony targets. A phony target is a target that is not really the name of a file. The rules following a phony target are executed unconditionally, regardless of whether a file with that name exists or what its last-modification time is.</p> <p>For example:</p> <pre>.PHONY: clean clean: rm *.o</pre> <p>With <code>amk clean</code>, the command is executed regardless of whether there is a file named <code>clean</code>.</p>

6.2.2. Makefile Directives

Directives inside makefiles are executed while reading the makefile. When a line starts with the word "include" or "-include" then the remaining arguments on that line are considered filenames whose contents are to be inserted at the current line. "-include" will silently skip files which are not present. You can include several files. Include files may be nested.

Example:

```
include makefile2 makefile3
```

White spaces (tabs or spaces) in front of the directive are allowed.

6.2.3. Macro Definitions

A *macro* is a symbol name that is replaced with its definition before the makefile is executed. Although the macro name can consist of lowercase or uppercase characters, uppercase is an accepted convention. When a line does not start with white space and contains the assignment operator '=', ':=' or '+=' then the line is interpreted as a macro definition. White space around the assignment operator and white space at the end of the line is discarded. Single character macro evaluation happens by prefixing the name with '\$'. To evaluate macros with names longer than one character put the name between parentheses '()' or curly braces '{}'. Macro names may contain anything, even white space or other macro evaluations.

Example:

```
DINNER = $(FOOD) and $(BEVERAGE)
FOOD = pizza
BEVERAGE = sparkling water
FOOD += with cheese
```

With the += operator you can add a string to an existing macro. An extra space is inserted before the added string automatically.

TASKING VX-toolset for MCS User Guide

Macros are evaluated recursively. Whenever `$(DINNER)` or `${DINNER}` is mentioned after the above, it will be replaced by the text "pizza with cheese and sparkling water". The left hand side in a macro definition is evaluated before the definition takes place. Right hand side evaluation depends on the assignment operator:

- = Evaluate the macro at the moment it is used.
- := Evaluate the replacement text before defining the macro.

Subsequent '+=' assignments will inherit the evaluation behavior from the previous assignment. If there is none, then '+=' is the same as '='. The default value for any macro is taken from the environment. Macro definitions inside the makefile overrule environment variables. Macro definitions on the **amk** command line will be evaluated first and overrule definitions inside the makefile.

Predefined macros

Macro	Description
\$	This macro translates to a dollar sign. Thus you can use "\$\$" in the makefile to represent a single "\$".
@	The name of the current target. When a rule has multiple targets, then it is the name of the target that caused the rule commands to be run.
*	The basename (or stem) of the current target. The stem is either provided via a static pattern rule or is calculated by removing all characters found after and including the last dot in the current target name. If the target name is 'test.c' then the stem is 'test' (if the target was not created via a static pattern rule).
<	The name of the first prerequisite.
MAKE	The amk path name (quoted if necessary). Optionally followed by the options -n and -s .
ORIGIN	The name of the directory where amk is installed (quoted if necessary).
SUBDIR	The argument of option -G . If you have nested makes with -G options, the paths are combined. This macro is defined in the environment (i.e. default macro value).

The @, * and < macros may be suffixed by 'D' to specify the directory component or by 'F' to specify the filename component. `$(@D)` evaluates to the directory name holding the file `$(@F)`. `$(@D)/$(@F)` is equivalent to `$(@)`. Note that on MS-Windows most programs accept forward slashes, even for UNC path names.

The result of the predefined macros @, * and < and 'D' and 'F' variants is not quoted, so it may be necessary to put quotes around it.

Note that stem calculation can cause unexpected values. For example:

\$(@)	\$(*)
/home/.wine/test	/home/
/home/test/.project	/home/test/
../file	/.

Macro string substitution

When the macro name in an evaluation is followed by a colon and equal sign as in

```
$(MACRO:string1=string2)
```

then **amk** will replace *string1* at the end of every word in $\$(MACRO)$ by *string2* during evaluation. When $\$(MACRO)$ contains quoted path names, the quote character must be mentioned in both the original string and the replacement string¹. For example:

```
$(MACRO:.o=".d")
```

6.2.4. Makefile Functions

A function not only expands but also performs a certain operation. The following functions are available:

$\$(filter\ pattern\ \dots,item\ \dots)$

The `filter` function filters a list of items using a pattern. It returns *items* that do match any of the *pattern* words, removing any items that do not match. The patterns are written using '%',

```
#{filter %.c %.h, test.c test.h test.o readme.txt .project output.c}
```

results in:

```
test.c test.h output.c
```

$\$(filter-out\ pattern\ \dots,item\ \dots)$

The `filter-out` function returns all *items* that do not match any of the *pattern* words, removing the items that do match one or more. This is the exact opposite of the `filter` function.

```
#{filter-out %.c %.h, test.c test.h test.o readme.txt .project output.c}
```

results in:

```
test.o readme.txt .project
```

$\$(foreach\ var-name,\ item\ \dots,\ action)$

The `foreach` function runs through a list of items and performs the same *action* for each *item*. The *var-name* is the name of the macro which gets dynamically filled with an item while iterating through the *item* list. In the *action* you can refer to this macro. For example:

```
#{foreach T, test filter output, ${T}.c ${T}.h}
```

results in:

```
test.c test.h filter.c filter.h output.c output.h
```

¹Internally, **amk** tokenizes the evaluated text, but performs substitution on the original input text to preserve compatibility here with existing make implementations and POSIX.

6.2.5. Conditional Processing

Lines containing `ifdef`, `ifndef`, `else` or `endif` are used for conditional processing of the makefile. They are used in the following way:

```
ifdef macro-name
if-lines
else
else-lines
endif
```

The *if-lines* and *else-lines* may contain any number of lines or text of any kind, even other `ifdef`, `ifndef`, `else` and `endif` lines, or no lines at all. The `else` line may be omitted, along with the *else-lines* following it. White spaces (tabs or spaces) in front of preprocessing directives are allowed.

First the *macro-name* after the `ifdef` command is checked for definition. If the macro is defined then the *if-lines* are interpreted and the *else-lines* are discarded (if present). Otherwise the *if-lines* are discarded; and if there is an `else` line, the *else-lines* are interpreted; but if there is no else line, then no lines are interpreted.

When you use the `ifndef` line instead of `ifdef`, the macro is tested for not being defined. These conditional lines can be nested to any level.

You can also add tests based on strings. With `ifeq` the result is true if the two strings match, with `ifneq` the result is true if the two strings do not match. They are used in the following way:

```
ifeq(string1,string2)
if-lines
else
else-lines
endif
```

6.2.6. Makefile Parsing

amk reads and interprets a makefile in the following order:

1. When the last character on a line is a backslash (`\`) (i.e. without trailing white space) then that line and the next line will be concatenated, removing the backslash and newline.
2. The unquoted `#` character indicates start of comment and may be placed anywhere on a line. It will be removed in this phase.

```
# this comment line is continued\  
on the next line
```

3. Trailing white space is removed.
4. When a line starts with white space and it is not followed by a directive or preprocessing directive, then it is interpreted as a command for updating a target.

5. Otherwise, when a line contains the unquoted text '=', '+=' or ':=' operator, then it will be interpreted as a macro definition.
6. Otherwise, all macros on the line are evaluated before considering the next steps.
7. When the resulting line contains an unquoted ':' the line is interpreted as a dependency rule.
8. When the first token on the line is "include" or "-include" (which by now must start on the first column of the line), **amk** will execute the directive.
9. Otherwise, the line must be empty.

Macros in commands for updating a target are evaluated right before the actual execution takes place (or would take place when you use the **-n** option).

6.2.7. Makefile Command Processing

A line with leading white space (tabs or spaces) without a (preprocessing) directive is considered as a command for updating a target. When you use the option **-j** or **-J**, **amk** will execute the commands for updating different targets in parallel. In that case standard input will not be available and standard output and error output will be merged and displayed on standard output only after the commands have finished for a target.

You can precede a command by one or more of the following characters:

- @ Do not show the command. By default, commands are shown prior to their output.
- Continue upon error. This means that **amk** ignores a non-zero exit code of the command.
- + Execute the command, even when you use option **-n** (dry run).
- | Execute the command on the foreground with standard input, standard output and error output available.

Built-in commands

Command	Description
true	This command does nothing. Arguments are ignored.
false	This command does nothing, except failing with exit code 1. Arguments are ignored.
echo <i>arg...</i>	Display a line of text.
exit <i>code</i>	Exit with defined code. Depending on the program arguments and/or the extra rule options '-' this will cause amk to exit with the provided code. Please note that 'exit 0' has currently no result.
argfile <i>file arg...</i>	Create an argument file suitable for the --option-file (-f) option of all the other tools. The first <i>argfile</i> argument is the name of the file to be created. Subsequent arguments specify the contents. An existing argument file is not modified unless necessary. So, the argument file itself can be used to create a dependency to options of the command for updating a target.

Command	Description
<code>rm [option]... file...</code>	Remove the specified file(s). The following options are available: <ul style="list-style-type: none"> -r, --recursive Remove directories and their contents recursively. -f, --force Force deletion. Ignore non-existent files, never prompt. -i, --interactive Interactive. Prompt before every removal. -v, --verbose Verbose mode. Explain what is being done. -m file Read options from <i>file</i>.. -?, --help Show usage.

6.2.8. Calling the amk Make Utility

The invocation syntax of **amk** is:

```
amk [option]... [target]... [macro=def]...
```

For example:

```
amk test.elf
```

- target* You can specify any target that is defined in the makefile. A target can also be one of the intermediate files specified in the makefile.
- macro=def* Macro definition. This definition remains fixed for the **amk** invocation. It overrides any regular definitions for the specified macro within the makefiles and from the environment. It is not inherited by subordinate **amk**'s
- option* For a complete list and description of all **amk** make utility options, see [Section 8.5, Parallel Make Utility Options](#).

Exit status

The make utility returns an exit status of 1 when it halts as a result of an error. Otherwise it returns an exit status of 0.

6.3. Archiver

The archiver **armcs** is a program to build and maintain your own library files. A library file is a file with extension `.a` and contains one or more object files (`.o`) that may be used by the linker.

The archiver has five main functions:

- Deleting an object module from the library
- Moving an object module to another position in the library file
- Replacing an object module in the library or add a new object module
- Showing a table of contents of the library file
- Extracting an object module from the library

The archiver takes the following files for input and output:

The linker optionally includes object modules from a library if that module resolves an external symbol definition in one of the modules that are read before.

6.3.1. Calling the Archiver

You can create a library in Eclipse, which calls the archiver or you can call the archiver on the command line.

To create a library in Eclipse

Instead of creating an MCS absolute ELF file, you can choose to create a library. You do this when you create a new project with the New C Project wizard.

1. From the **File** menu, select **New » TASKING MCS C Project**.
The New C Project wizard appears.
2. Enter a project name.
3. In the **Project type** box, select **TASKING MCS Library** and click **Next >**.
4. Follow the rest of the wizard and click **Finish**.

TASKING VX-toolset for MCS User Guide

5. Add the files to your project.
6. Build the project as usual. For example, select **Project » Build Project** ()

Eclipse builds the library. Instead of calling the linker, Eclipse now calls the archiver.

Command line invocation

You can call the archiver from the command line. The invocation syntax is:

```
armcs key_option [sub_option...] library [object_file]
```

<i>key_option</i>	With a key option you specify the main task which the archiver should perform. You must <i>always</i> specify a key option.
<i>sub_option</i>	Sub-options specify into more detail how the archiver should perform the task that is specified with the key option. It is not obligatory to specify sub-options.
<i>library</i>	The name of the library file on which the archiver performs the specified action. You must always specify a library name, except for the options -? and -V . When the library is not in the current directory, specify the complete path (either absolute or relative) to the library.
<i>object_file</i>	The name of an object file. You must always specify an object file name when you add, extract, replace or remove an object file from the library.

Options of the archiver utility

The following archiver options are available:

Description	Option	Sub-option
Main functions (key options)		
Replace or add an object module	-r	-a -b -c -n -u -v
Extract an object module from the library	-x	-o -v
Delete object module from library	-d	-v
Move object module to another position	-m	-a -b -v
Print a table of contents of the library	-t	-s0 -s1
Print object module to standard output	-p	
Sub-options		
Append or move new modules after existing module <i>name</i>	-a name	
Append or move new modules before existing module <i>name</i>	-b name	
Suppress the message that is displayed when a new library is created	-c	
Create a new library from scratch	-n	
Preserve last-modified date from the library	-o	
Print symbols in library modules	-s{0 1}	

Description	Option	Sub-option
Replace only newer modules	-u	
Verbose	-v	
Miscellaneous		
Display options	-?	
Display description of one or more diagnostic messages	--diag	
Display version header	-V	
Read options from <i>file</i>	-f file	
Suppress warnings above level <i>n</i>	-wn	

For a complete list and description of all archiver options, see [Section 8.6, Archiver Options](#).

6.3.2. Archiver Examples

Create a new library

If you add modules to a library that does not yet exist, the library is created. To create a new library with the name `mylib.a` and add the object modules `cstart.o` and `calc.o` to it:

```
armcs -r mylib.a cstart.o calc.o
```

Add a new module to an existing library

If you add a new module to an existing library, the module is added at the end of the module. (If the module already exists in the library, it is replaced.)

```
armcs -r mylib.a mod3.o
```

Print a list of object modules in the library

To inspect the contents of the library:

```
armcs -t mylib.a
```

The library has the following contents:

```
cstart.o
calc.o
mod3.o
```

Move an object module to another position

To move `mod3.o` to the beginning of the library, position it just before `cstart.o`:

```
armcs -mb cstart.o mylib.a mod3.o
```

Delete an object module from the library

To delete the object module `cstart.o` from the library `mylib.a`:

```
armcs -d mylib.a cstart.o
```

Extract all modules from the library

Extract all modules from the library `mylib.a`:

```
armcs -x mylib.a
```

6.4. HLL Object Dumper

The high level language (HLL) dumper **hldumpmcs** is a program to dump information about an absolute object file (`.elf`). Key features are a disassembler with HLL source intermixing and HLL symbol display and a HLL symbol listing of static and global symbols.

6.4.1. Invocation

Command line invocation

You can call the HLL dumper from the command line. The invocation syntax is:

```
hldumpmcs [option]... file...
```

The input file must be an ELF file with or without DWARF debug info (`.elf`).

The HLL dumper can process multiple input files. Files and options can be intermixed on the command line. Options apply to all supplied files. If multiple files are supplied, the disassembly of each file is preceded by a header to indicate which file is dumped. For example:

```
===== file.elf =====
```

For a complete list and description of all options, see [Section 8.7, HLL Object Dumper Options](#). With `hldumpmcs --help` you will see the options on `stdout`.

6.4.2. HLL Dump Output Format

The HLL dumper produces output in text format by default, but you can also specify the XML output format with option `--output-type=xml`. The XML output is mainly for use in the Eclipse editor. Alternatively, you can use option `--adx-format` to produce output in the ADX address list format. For more information about this format, see *ADX Specification - Address List Format for A2L Address Calculation - Compiler vendors, Version 1.10, 2015-04-27*.

The output is printed on `stdout`, unless you specify an output file with `--output=filename`.

The parts of the output are dumped in the following order:

1. Module list
2. Section list
3. Call graph using the DWARF debug info
4. Section dump (disassembly)
5. HLL symbol table
6. Assembly level symbol table
7. Note sections
8. Debug control flow section

TASKING VX-toolset for MCS User Guide

With the option `--dump-format=flag` you can control which parts are shown. By default, all parts are shown, except for parts 3 and 8.

Example

Suppose we have a simple "Hello World" program in a file called `hello.c`. We call the control program as follows:

```
ccmcs -g -t --control-flow-info hello.c
```

Option `-g` tells to include DWARF debug information. Option `-t` tells to keep the intermediate files. Option `--control-flow-info` adds control flow information to the output file. This command results (among other files) in the file `hello.elf` (the absolute object file).

We can dump information about the ELF file with the following command:

```
hldumpmcs -F3 hello.elf
```

Option `-F3` enables all parts. A possible output could be (just a fraction of the actual output is shown):

```
----- Module list -----  
  
Name      Full path  
hello.c   hello.c  
  
----- Section list -----  
  
Address  Size  Align Type      Name  
000003f4   28    4 text    .mcstext.hello.main  
000002b8   24    4 data    .mcsdata.hello.$1$str  
00000300    4    4 data    .mcsdata.hello.world  
000002d0   48    4 data    .mcsdata.hello.$2$str  
  
----- Call graph using the DWARF debug info -----  
  
+-- 0x000003f4 main  
  |  
  +-- 0x0000092c printf  
    |  
    +-- 0x00000474 _doprint  
      |  
      +-- 0x00000840 _io_putc  
        |  
        +-- 0x00000900 fputc  
          |  
          +-- 0x0000067c _flsbuf  
            |  
            +-- 0x00000820 _host_write  
              |  
              +-- 0x00000430 _dbg_trap
```

```

|           +-- 0x00000548 _fflush
|           |

Module list

This part lists all modules (C files) found in the object file(s). It lists the filename and the complete path name at the time the module was built.

Section list

This part lists all sections found in the object file(s).

Address	The start address of the section. Hexadecimal, 8 digits, 32-bit.
Size	The size (length) of the section in bytes. Decimal, filled up with spaces.
Align	The alignment of the section in number of bytes. Decimal, filled up with spaces.
Type	The section type.
Name	The name of the section.

With option `--sections=name[,name]...` you can specify a list of sections that should be dumped.

Call graph

The linker can generate a call graph in the linker map file. However, if you only have an ELF file and you need to test it, you can use the option **--dump-format=+callgraph**. You can then step through the call graph to identify the flow for debugging purposes. Some notes about the call graph:

- The call graph starts with the default entry point of the application.
- Recursive calls are marked with 'R'.
- Inline functions are marked with 'I'.
- A function is analyzed only once. When a function is called again, it is not analyzed again and this is marked with '!'.
 *!.
- By default the DWARF debug information is used to generate the call graph. When no DWARF information is available the ELF information is used. Inline functions can only be detected and dumped when DWARF information is available.
- With option **--call-graph-elf-mode** you can force the call graph to use ELF symbols even when DWARF information is available. This can be useful when you want to dump information from an assembly function.
- With option **--call-graph-root=function** you can specify the address or function name where to start the call graph (default: `main()`).

Section dump

This part contains the disassembly. It consists of the following columns:

address column	Contains the address of the instruction or directive that is shown in the disassembly. If the section is relocatable the section start address is assumed to be 0. The address is represented in hexadecimal and has a fixed width. The address is padded with zeros. No 0x prefix is displayed. For example, on a 32-bit architecture, the address 0x32 is displayed as 00000032.
encoding column	Shows the hexadecimal encoding of the instruction (code sections) or it shows the hexadecimal representation of data (data sections). The encoding column has a maximum width of eight digits, i.e. it can represent a 32-bit hexadecimal value. The encoding is padded to the size of the data or instruction. For example, a 16-bit instruction only shows four hexadecimal digits. The encoding is aligned left and padded with spaces to fill the eight digits.
label column	Displays the label depending on the option --symbols=[hll asm none] . The default is asm , meaning that the low level (ELF) symbols are used. With hll , HLL (DWARF) symbols are used. With none , no symbols will be included in the disassembly.

TASKING VX-toolset for MCS User Guide

disassembly column For code sections the instructions are disassembled. Operands are replaced with labels, depending on the option `--symbols=[hll|asm|none]`.

The contents of data sections are represented by directives. A new directive will be generated for each symbol. ELF labels in the section are used to determine the start of a directive. ROM sections are represented with `.word` directives. RAM sections are represented with `.space` directives. This can be either the size specified in the ELF symbol, or the size up to the next label.

With option `--hex`, no directives will be generated for ROM data sections and no disassembly dump will be done for code sections. Instead a hex dump is done with the following format:

```
AAAAAAAA H0 H1 H2 H3 H4 H5 H6 H7 H8 H9 HA HB HC HD HE HF RRRRRRRRRRRRRRRR
```

where,

A = Address (8 digits, 32-bit)

Hx = Hex contents, one byte (16 bytes max)

R = ASCII representation (16 characters max)

For example:

```
                                section 7 (.mcsdata.hello.$2$str):
000002d0 48 00 00 00 65 00 00 00 6c 00 00 00 6c 00 00 00 H...e...l...l...
000002e0 6f 00 00 00 2c 00 00 00 20 00 00 00 25 00 00 00 o...,... ..%...
000002f0 73 00 00 00 21 00 00 00 0a 00 00 00 00 00 00 00 s...!.....
```

With option `--hex`, RAM sections will be represented with only a start address and a size indicator:

```
AAAAAAAA Space: 24 bytes
```

With option `--disassembly-intermix` you can intermix the disassembly with HLL source code.

HLL symbol table

This part contains a symbol listing based on the HLL (DWARF) symbols found in the object file(s). The symbols are sorted on address.

Address	The start address of the symbol. Hexadecimal, 8 digits, 32-bit.
Size	The size of the symbol from the DWARF info in bytes.
HLL Type	The HLL symbol type.
Name	The name of the HLL symbol.

HLL arrays are indicated by adding the size in square brackets to the symbol name. For example:

```
00000038    320 static char          stdin_buf[80] [_iob.c]
```

With option `--expand-symbols=+basic-types` HLL struct and union symbols are listed including all fields. Array members are expanded in one array member per line regardless of the HLL type. For example:

```
00000038      320 static char          stdin_buf[80] [_iob.c]
00000038        4   char
0000003c        4   char
00000040        4   char
...
00000174        4   char
```

HLL struct and union symbols are listed by default without fields. For example:

```
00000020      24 struct              _dbg_request [dbg.c]
```

With option `--expand-symbols` all struct, union and array fields are included as well. For the fields the types and names are indented with two spaces. For example:

```
00000020      24 struct              _dbg_request [dbg.c]
00000020        4   int                _errno
00000024        4   enum              nr
00000028       16   union              u
00000028        4     struct            exit
00000028        4     int              status
00000028        8     struct            open
00000028        4     const char      * pathname
0000002c        4     unsigned int    flags
...
```

Functions are displayed with the full function prototype. Size is the size of the function. HLL Type is the return type of the function. For example:

```
0000092c      56 int                printf(const char * restrict format, ...)
```

The local and static symbols get an identification between square brackets. The filename is printed and if a function scope is known the function name is printed between the square brackets as well. If multiple files with the same name exist, the unique part of the path is added. For example:

```
00000200        4 int                count [file.c, somefunc()]
00000204        4 int                count [x\a.c]
00000208        4 int                count [y\a.c, foo()]
```

Global symbols do not get information in square brackets.

Assembly level symbol table

This part contains a symbol listing based on the assembly level (ELF) symbols found in the object file(s). The symbols are sorted on address.

Address	The start address of the symbol. Hexadecimal, 8 digits, 32-bit.
Size	The size of the symbol from the ELF info in bytes. If this field is empty, the size is zero.

Type	Code or Data, depending on the section the symbol belongs to. If this field is empty, the symbol does not belong to a section.
Name	The name of the ELF symbol.

Debug control flow section

When control flow information is present in the ELF file ([control program option `--control-flow-info`](#)), this part shows information about the basic blocks and their relation.

start offset	The start seek offset in bytes from the beginning of the section.
start address	The start address of the basic block.
code size	The code size of the basic block.
#entries	The number of successor basic blocks. This value can be 0 if there are no successors.
dest. offset	The destination offset in bytes to the first, second, ... successor from the beginning of the section.

6.5. Bosch MCS Assembly to TASKING Assembly Converter

The Perl script `cnvba2ta.pl` is a converter to convert Bosch MCS assembly files to TASKING VX-toolset for MCS assembly files. You need to have Perl installed on your system.

Command line invocation

You can call the converter from the command line by using Perl. The invocation syntax is:

```
perl cnvba2ta.pl input_file > output_file
```

Without output redirection the output is sent to `stdout`. The converted file includes `mcs_defines.inc`.

For example:

```
perl cnvba2ta.pl bosch_mcs.mcs > tsk_mcs.asm
```

Chapter 7. Using the Debugger

This chapter describes the debugger and how you can run and debug a C application. This chapter only describes the TASKING specific parts.

7.1. Reading the Eclipse Documentation

Before you start with this chapter, it is recommended to read the Eclipse documentation first. It provides general information about the debugging process. This chapter guides you through a number of examples using the TASKING debugger with simulation as target.

You can find the Eclipse documentation as follows:

1. Start Eclipse.
2. From the **Help** menu, select **Help Contents**.
The help screen overlays the Eclipse Workbench.
3. In the left pane, select **C/C++ Development User Guide**.
4. Open the **Getting Started** entry and select **Debugging projects**.

This Eclipse tutorial provides an overview of the debugging process. Be aware that the Eclipse example does not use the TASKING tools and TASKING debugger.

7.2. Creating a Customized Debug Configuration

Before you can debug a project, you need a Debug launch configuration. Such a configuration, identified by a name, contains all information about the debug project: which debugger is used, which project is used, which binary debug file is used, which perspective is used, ... and so forth.

If you want to debug on a target board, you have to create a custom debug configuration for your target board, otherwise you have to create a debug launch configuration for the TASKING simulator.

To debug a project, you need at least one opened and active project in your workbench. In this chapter, it is assumed that the `myproject` is opened and active in your workbench.

Create or customize your debug configuration

To create or change a debug configuration follow the steps below.

1. From the **Debug** menu, select **Debug Configurations...**
The Debug Configurations dialog appears.
2. Select **TASKING C/C++ Debugger** and click the **New launch configuration** button ()

) to add a new configuration.

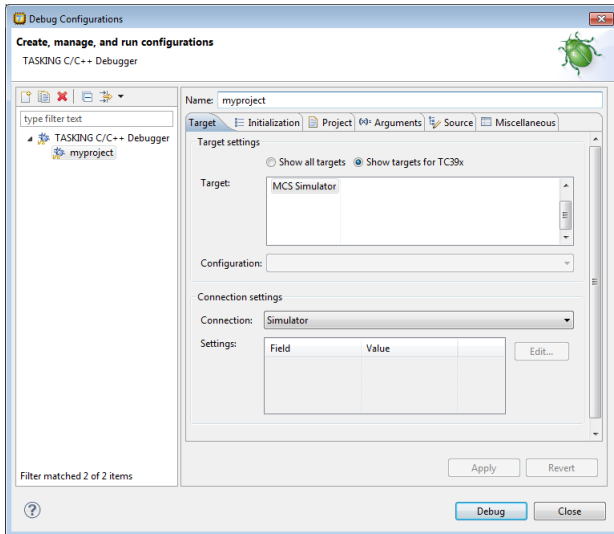

Or: In the left pane, select the configuration you want to change, for example, **TASKING C/C++ Debugger » myproject**.

3. In the **Name** field enter the name of the configuration. By default, this is the name of the project, but you can give your configuration any name you want to distinguish it from the project name. For example enter `myproject.simulator` to identify the simulator debug configuration.
4. On the **Target** tab, select the **MCS Simulator** or any of the target boards.

The dialog shows several tabs.

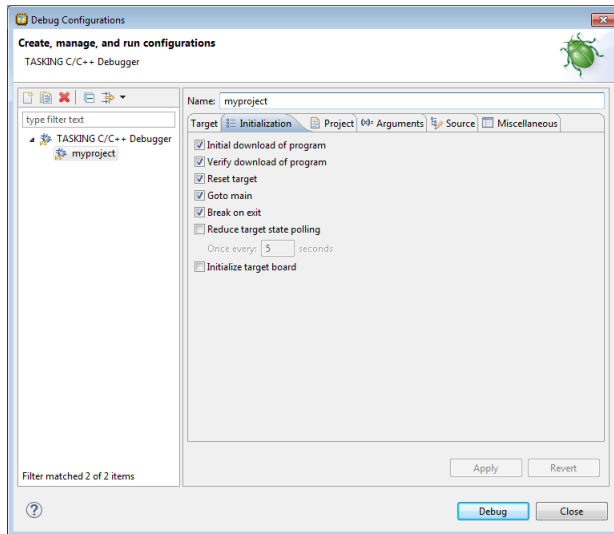

Target tab

On the **Target** tab you can select on which target the application should be debugged. An application can run on an external evaluation board, or on a simulator using your own PC. On this tab you can also select the connection settings. The information in this tab is based on the Debug Target Configuration (DTC) files as explained in [Chapter 14, Debug Target Configuration Files](#).

Initialization tab

On the **Initialization** tab enable one or more of the following options:

- **Initial download of program**

If enabled, the target application is downloaded onto the target. If disabled, only the debug information in the file is loaded, which may be useful when the application has already been downloaded (or flashed) earlier. If downloading fails, the debugger will shut down.

- **Verify download of program**

If enabled, the debugger verifies whether the code and data has been downloaded successfully. This takes some extra time but may be useful if the connection to the target is unreliable.

- **Reset target**

If enabled, the target is immediately reset after downloading has completed. Registers that have the `init` resource set in the `.dtc` file, are reset to their default value. Execution stops at the reset vector `__START()`.

- **Goto main**

If enabled, only the C startup code is processed when the debugger is launched. The application stops executing when it reaches the first C instruction in the function `main()`. Usually you enable this option in combination with the option **Reset Target**.

- **Break on exit**

If enabled, the target halts automatically when the `exit()` function is called.

- **Reduce target state polling**

If you have set a breakpoint, the debugger checks the status of the target every *number* of seconds to find out if the breakpoint is hit. In this field you can change the polling frequency.

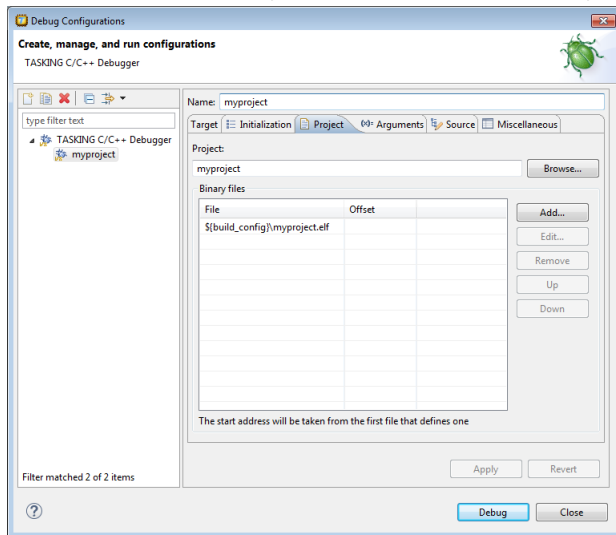

• Initialize Target Board

Some target boards contain a power supply chip which needs to be initialized every time after power-on, before hardware debugging is started. If enabled, the target board is initialized automatically before the start of a debug session.

This option is not supported for the MCS.

Project tab

On the **Project** tab, you can set the properties for the debug configuration such as a name for the project and the application binary file(s) which are used when you choose this configuration.

- In the **Project** field, you can choose the project for which you want to make a debug configuration. Because the project `myproject` is the active project, this project is filled in automatically. Click the **Browse...** button to select a different project. Only the *opened* projects in your workbench are listed.
- In the **Binary files** group box, you can choose one or more binary files to debug. The file `myproject.elf` is automatically selected from the active project.

The order of the binary files matters. Use the **Up** and **Down** buttons to change the order. If there are multiple files, the application start address is taken from the first file that defines one. An ELF file always defines one, whereas Hex files may not.

Note that conflicts between symbols could arise, for example when you download two ELF files that both contain the function `main()`. When you download multiple files, we recommend that the first binary file is an ELF file that contains the startup code and `main()` and that the other files are auxiliary Hex files.

To add a binary file

1. Click **Add...** to add a binary file.

The Add Binary File dialog appears.

2. Specify the binary file, use the **Search...** button to select one from the active project, or use the **Browse...** button to search the file system.
3. Optionally, specify an address offset. The value will be added to all target addresses in the binary file.

Note that the address offset will be applied only to code, data and the start address, not to debug information. Specifying a non-zero offset is not recommended for an ELF/DWARF file. If the offset causes an address to underflow or overflow an error occurs.

Arguments tab

If your application's `main()` function takes arguments, you can pass them in this tab. Arguments are conventionally passed in the `argv[]` array. Because this array is allocated in target memory, make sure you have allocated sufficient memory space for it.

Source tab

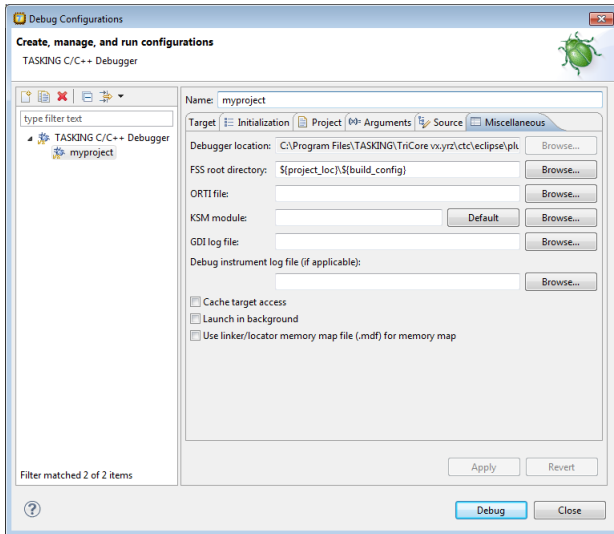

On the **Source** tab, you can add additional source code locations in which the debugger should search for debug data.

- Usually, the default source code location is correct.

Miscellaneous tab

On the **Miscellaneous** tab you can specify several file locations.

- **Debugger location**

The location of the debugger itself. This should not be changed.

- **FSS root directory**

The initial directory used by file system simulation (FSS) calls. See the description of the [FSS view](#).

- **ORTI file and KSM module**

If you wish to use the debugger's special facilities for kernel-aware debugging, specify the name of a Kernel Debug Interface (KDI) compatible KSM module (shared library) in the appropriate edit box. See also the description of the [RTOS view](#).

- **GDI log file and Debug instrument log file**

You can use the options GDI log file and Debug instrument log file (if applicable) to control the generation of internal log files. These are primarily intended for use by or at the request of Altium support personnel.

- **Cache target access**

Except when using a simulator, the debugger's performance is generally strongly dependent on the throughput and latency of the connection to the target. Depending on the situation, enabling this option may result in a noticeable improvement, as the debugger will then avoid re-reading registers and memory while the target remains halted. However, be aware that this may cause the debugger to show the wrong data if tasks with a higher priority or external sources can influence the halted target's state.

- **Launch in background**

When this option is disabled you will see a progress bar when the debugger starts. If you do not want to see the progress bar and want that the debugger launches in the background you can enable this option.

- **Use linker/locator memory map file (.mdf) for memory map**

You can use this option to find errors in your application that cause access to non-existent memory or cause an attempt to write to read-only memory. When building your project, the linker/locator creates a memory description file (.mdf) file which describes the memory regions of the target you selected in your project properties. The debugger uses this file to initialize the debugging target.

This option is only useful in combination with a simulator as debug target. The debugger may fail to start if you use this option in combination with other debugging targets than a simulator.

7.3. Troubleshooting

If the debugger does not launch properly, this is likely due to mistakes in the settings of the execution environment or to an improper connection between the host computer and the execution environment. Always read the notes for your particular execution environment.

Some common problems you may check for, are:

Problem	Solution
Wrong device name in the launch configuration	Make sure the specified device name is correct.
Invalid baud rate	Specify baud rate that matches the baud rate the execution environment is configured to expect.
No power to the execution environment.	Make sure the execution environment or attached probe is powered.
Cable connected to the wrong port on the execution environment or host.	Some target machines and hosts have several ports. Make sure you connect the cable to the correct port.
Conflict between communication ports.	A device driver or background application may use the same communications port on the host system as the debugger. Disable any service that uses the same port-number or choose a different port-number if possible.
Port already in use by another user.	The port may already be in use by another user on some UNIX hosts, or being allocated by a login process. Some target machines and hosts have several ports. Make sure you connect the cable to the correct port.

7.4. TASKING Debug Perspective

After you have launched the debugger, you are either asked if the TASKING Debug perspective should be opened or it is opened automatically. The Debug perspective consists of several views.

To open views in the Debug perspective:

1. Make sure the Debug perspective is opened
2. From the **Window** menu, select **Show View »**
3. Select a view from the menu or choose **Other...** for more views.

By default, the Debug perspective is opened with the following views:

7.4.1. Debug View

The Debug view shows the target information in a tree hierarchy shown below with a sample of the possible icons:

Icon	Session item	Description
	Launch instance	Launch configuration name and launch type
	Debugger instance	Debugger name and state
	Thread instance	Thread number and state
	Stack frame instance	Stack frame number, function, file name, and file line number

Stack display

During debugging (running) the actual stack is displayed as it increases or decreases during program execution. By default, all views present information that is related to the current stack item (variables, memory, source code etc.). To obtain the information from other stack items, click on the item you want.

TASKING VX-toolset for MCS User Guide

The Debug view displays stack frames as child elements. It displays the reason for the suspension beside the thread, (such as end of stepping range, breakpoint hit, and signal received). When a program exits, the exit code is displayed.

The Debug view contains numerous functions for controlling the individual stepping of your programs and controlling the debug session. You can perform actions such as terminating the session and stopping the program. All functions are available from the right-click menu, though commonly used functions are also available from the toolbar.

Controlling debug sessions

Icon	Action	Description
	Remove all	Removes all terminated launches.
	Reset target system	Resets the target system. Registers that have the <code>init</code> resource set in the <code>.dtc</code> file, are reset to their default value. Execution stops at the reset vector <code>__START()</code> .
	Restart	Resets the target system and restarts the application. The application stops executing when it reaches the first C instruction in the function <code>main()</code> .
	Resume	Resumes the application after it was suspended (manually, breakpoint, signal).
	Suspend	Suspends the application (pause). Use the Resume button to continue.
	Relaunch	Right-click menu. Restarts the selected debug session when it was terminated. If the debug session is still running, a new debug session is launched.
	Reload current application	Reloads the current application without restarting the debug session. The application does restart of course.
	Terminate	Ends the selected debug session and/or process. Use Relaunch to restart this debug session, or start another debug session.
	Terminate all	Right-click menu. As terminate. Ends <i>all</i> debug sessions.
	Terminate and remove	Right-click menu. Ends the debug session and removes it from the Debug view.
	Terminate and Relaunch	Right-click menu. Ends the debug session and relaunches it. This is the same as choosing Terminate and then Relaunch.
	Disconnect	Detaches the debugger from the selected process (useful for debugging attached processes).

Stepping through the application

Icon	Action	Description
	Step into	Steps to the next source line or instruction.
	Step over	Steps over a called function. The function is executed and the application suspends at the next instruction after the call.

Icon	Action	Description
	Step return	Executes the current function. The application suspends at the next instruction after the return of the function.
	Instruction stepping	Toggle. If enabled, the stepping functions are performed on instruction level instead of on C source line level.
	Interrupt aware stepping	Toggle. If an interrupt source continues generating interrupts while the target is stopped (either manually or by hitting a breakpoint), a following single step will always enter the Interrupt Service Routine (ISR). This can lead to some problems during single stepping. With interrupt aware stepping enabled, interrupts are temporarily disabled after the target has stopped. When execution resumes the interrupts are restored.

Miscellaneous

Icon	Action	Description
	Copy Stack	Right-click menu. Copies the stack as text to the windows clipboard. You can paste the copied selection as text in, for example, a text editor.
	Edit <i>project</i> ...	Right-click menu. Opens the debug configuration dialog to let you edit the current debug configuration.
	Edit Source Lookup...	Right-click menu. Opens the Edit Source Lookup Path window to let you edit the search path for locating source files.

7.4.2. Breakpoints View

You can add, disable and remove breakpoints by clicking in the marker bar (left margin) of the Editor view. This is explained in the Getting Started manual.

Description

The Breakpoints view shows a list of breakpoints that are currently set. The button bar in the Breakpoints view gives access to several common functions. The right-most button  opens the Breakpoints menu.

Types of breakpoints

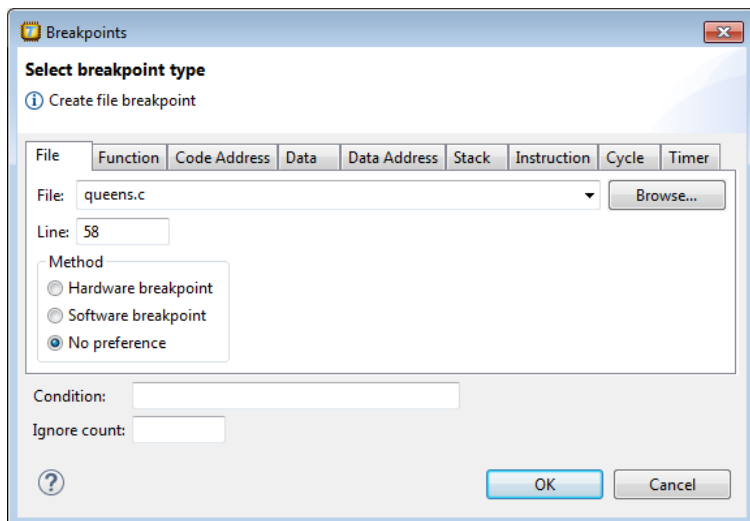

To access the breakpoints dialog, add a breakpoint as follows:

1. Click the **Add TASKING Breakpoint** button (.

The Breakpoints dialog appears.

Each tab lets you set a breakpoint of a specific type. You can set the following types of breakpoints:

- File breakpoint

If a debug session is active, the **File** drop-down box is filled with all source files as present in the debug information in the ELF file. This can include files not present in the Eclipse project (for example from libraries). If a file could be matched to a file in the active Eclipse project it will show as an Eclipse project relative filename.

The target halts when it reaches the specified line of the specified source file. Note that it is possible that a source line corresponds to multiple addresses, for example when a header file has been included into two different source files or when inlining has occurred. If so, the breakpoint will be associated with all those addresses. It is also possible that on some files no line breakpoints can be set because the debugger lacks line information.

- **Function**

The **Function** drop-down box is filled with all functions from the debug information and the symbol table (if not already in the debug information). You can use the **File** drop-down box to filter the list of functions. If you select **<all>** you will see the filenames (between parentheses) behind each entry in the **Function** drop-down box. Functions marked with *function_name [section]* originate from the symbol table. These functions are normally not associated with a filename and will therefore be included if **<unknown>** is selected in the **File** drop-down box. Functions marked *'filename'::function_name* are static functions.

The target halts when it reaches the first line of the specified function. Note that function breakpoints generally will not work on inlined instances of a function.

- **Code Address**

The target halts when it reaches the specified instruction address.

- **Data**

The **Variable** drop-down box is filled with all variables from the debug information and the symbol table (if not already in the debug information), but you can also enter text yourself. If a label is filled in, the size will be 1 MAU. You can use the **File** drop-down box to filter the list of variables. If you select **<all>** you will see the filenames (between parentheses) behind each entry in the **Variables** drop-down box. Variables marked with *variable_name* [section] originate from the symbol table. These variables are

normally not associated with a filename and will therefore be included if **<unknown>** is selected in the **File** drop-down box. Variables marked '*filename*::*variable_name*' are static.

The target halts when the given variable is read or written to, as specified.

- **Data Address**

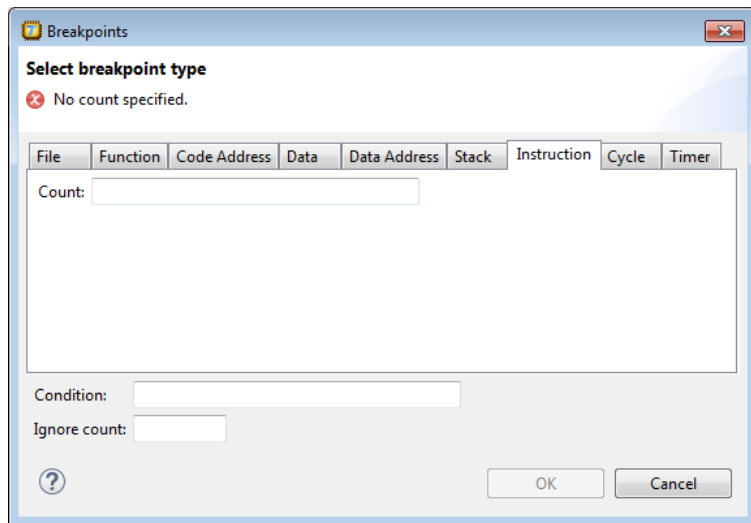

The target halts when the given memory range (specified in terms of an absolute **Address** and a **Length** in MAUs) is read or written to, as specified.

- **Stack**

The target halts when it reaches the specified stack level.

- **Instruction**

The target halts when the given number of instructions (**Count**) has been executed.

- **Cycle**

The target halts when the given number of clock cycles (**Count**) has elapsed.

- **Timer**

The target halts when the given amount of **Time** elapsed. The value entered is interpreted by the debug instrument.

In addition to the type of the breakpoint, you can specify the condition that must be met to halt the program.

In the **Condition** field, type a condition. The condition is an expression which evaluates to 'true' (non-zero) or 'false' (zero). The program only halts on the breakpoint if the condition evaluates to 'true'.

In the **Ignore count** field, you can specify the number of times the breakpoint is ignored before the program halts. For example, if you want the program to halt only in the fifth iteration of a while-loop, type '4': the first four iterations are ignored.

7.4.3. File System Simulation (FSS) View

The File System Simulation (FSS) view is automatically opened when the target requests FSS input or generates FSS output. The virtual terminal that the FSS view represents, follows the VT100 standard. If you right-click in the view area of the FSS view, a menu is presented which gives access to some self-explanatory functions.

Per debugging session, you can have more than one FSS view, each of which is associated with a positive integer. By default, the view "FSS #1" is associated with the standard streams `stdin`, `stdout`, `stderr` and `stdaux`. Other views can be accessed by opening a file named "terminal window <number>", as shown in the example below.

```
FILE * f3 = fopen("terminal window 3", "rw");
fprintf(f3, "Hello, window 3.\n");
fclose(f3);
```

You can set the initial working directory of the target application in the Debug configuration dialog (see also [Section 7.2, Creating a Customized Debug Configuration](#)):

TASKING VX-toolset for MCS User Guide

1. On the **Debugger** tab, select the **Miscellaneous** sub-tab.
2. In the **FSS root directory** field, specify the FSS root directory.

The FSS implementation is designed to work without user intervention. Nevertheless, there are some aspects that you need to be aware of.

First, the interaction between the C library code (in the files `dbg*.c` and `dbg*.h`; see [Section 10.1.4, `dbg.h`](#)) and the debugger takes place via a breakpoint, which incidentally is not shown in the Breakpoints view. Depending on the situation this may be a hardware breakpoint, which may be in short supply.

Secondly, proper operation requires certain code in the C library to have debug information. This debug information should normally be present but might get lost when this information is stripped later in the development process.

7.4.4. Disassembly View

The Disassembly view shows target memory disassembled into instructions and / or data. If possible, the associated C / C++ source code is shown as well. The **Address** field shows the address of the current selected line of code.

To view the contents of a specific memory location, type the address in the **Address** field. If the address is invalid, the field turns red.

7.4.5. Expressions View

The Expressions view allows you to evaluate and watch regular C expressions.

To add an expression:

Click **OK** to add the expression.

1. Right-click in the Expressions View and select **Add Watch Expression**.

The Add Watch Expression dialog appears.

2. Enter an expression you want to watch during debugging, for example, the variable name "i"

If you have added one or more expressions to watch, the right-click menu provides options to **Remove** and **Edit** or **Enable** and **Disable** added expressions.

- You can access target registers directly using `#NAME`. For example `"arr[#R0 << 3]"` or `"#TIMER3 = mm++"`. If a register is memory-mapped, you can also take its address, for example, `"&#ADCIN"`.
- Expressions may contain target function calls like for example `"g1 + invert(&g2)"`. Be aware that this will not work if the compiler has optimized the code in such a way that the original function code does not actually exist anymore. This may be the case, for example, as a result of inlining. Also, be aware that the function and its callees use the same stack(s) as your application, which may cause problems if there is too little stack space. Finally, any breakpoints present affect the invoked code in the normal way.

7.4.6. Memory View

Use the Memory view to inspect and change process memory. The Memory view supports the same addressing as the C language. You can address memory using expressions such as:

- `0x0847d3c`
- `(&y)+1024`
- `*ptr`

Monitors

To monitor process memory, you need to add a *monitor*:

1. In the Debug view, select a debug session. Selecting a thread or stack frame automatically selects the associated session.
2. Click the **Add Memory Monitor** button in the Memory Monitors pane.

The Monitor Memory dialog appears.

3. Type the address or expression that specifies the memory section you want to monitor and click **OK**.

The monitor appears in the monitor list and the Memory Renderings pane displays the contents of memory locations beginning at the specified address.

To remove a monitor:

1. In the Monitors pane, right-click on a monitor.
2. From the popup menu, select **Remove Memory Monitor**.

Renderings

You can inspect the memory in so-called *renderings*. A rendering specifies how the output is displayed: hexadecimal, ASCII, signed integer, unsigned integer or traditional. You can add or remove renderings per monitor. Though you cannot change a rendering, you can add or remove them:

1. Click the **New Renderings...** tab in the Memory Renderings pane.

The Add Memory Rendering dialog appears.

2. Select the rendering you want (**Traditional**, **Hex**, **ASCII**, **Signed Integer**, **Unsigned Integer** or **Hex Integer**) and click **Add Rendering(s)**.

To remove a rendering:

1. Right-click on a memory address in the rendering.
2. From the popup menu, select **Remove Rendering**.

Changing memory contents

In a rendering you can change the memory contents. Simply type a new value.

Warning: Changing process memory can cause a program to crash.

The right-click popup menu gives some more options for changing the memory contents or to change the layout of the memory representation.

7.4.7. Compare Application View

You can use the Compare Application view to check if the downloaded application matches the application in memory. Differences may occur, for example, if you changed memory addresses in the Memory view.

- To check for differences, click the **Compare** button.

7.4.8. Heap View

With the Heap view you can inspect the status of the heap memory. This can be illustrated with the following example:

```
string = (char *) malloc(100);
strcpy ( string, "abcdefgh" );
free (string);
```

If you step through these lines during debugging, the Heap view shows the situation after each line has been executed. Before any of these lines has been executed, there is no memory allocated and the Heap view is empty.

- After the first line the Heap view shows that memory is occupied, the description tells where the block starts, how large it is (100 MAUS) and what its content is (0x0, 0x0, ...).
- After the second line, "abcdefgh" has been copied to the allocated block of memory. The description field of the Heap view again shows the actual contents of the memory block (0x61, 0x62, ...).
- The third line frees the memory. The Heap view is empty again because after this line no memory is allocated anymore.

7.4.9. Logging View

Use the Logging view to control the generation of internal log files. This view is intended mainly for use by or at the request of Altium support personnel.

7.4.10. RTOS View

The debugger has special support for debugging real-time operating systems (RTOSs). This support is implemented in an RTOS-specific shared library called a *kernel support module* (KSM) or *RTOS-aware debugging module* (RADM). You have to create your own Run Time Interface (ORTI) and specify this file

on the **Miscellaneous** tab while configuring a customized debug configuration (see also [Section 7.2, Creating a Customized Debug Configuration](#)):

1. From the **Debug** menu, select **Debug Configurations...**

The Debug Configurations dialog appears.

2. In the left pane, select the configuration you want to change, for example, **TASKING C/C++ Debugger » myproject**.

Or: click the **New launch configuration** button (📄) to add a new configuration.

3. Open the **Miscellaneous** tab

4. In the **ORTI file** field, specify the name of your own ORTI file.

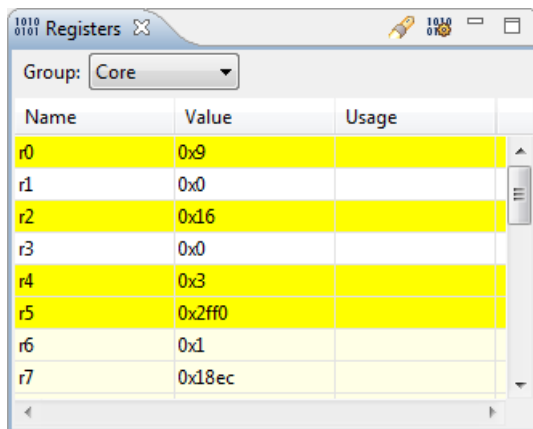

5. In the **KSM module** field, specify the name of a KSM shared library file suitable for RTOS kernels.

The debugger supports ORTI specifications v2.0 and v2.1.

7.4.11. Registers View

In the Registers view you can examine the value of registers while stepping through your application. The registers are organized in a number of *register groups*, which together contain all known registers. You can select a group to see which registers it contains. This view has a number of features:

- While you step through the application, the registers involved in the step turn yellow. If you scroll in the view or switch groups, some registers may appear on a lighter yellow background, indicating that the debugger does not know whether the registers have changed because the debugger did not read the registers before the step began.

- You can change each register's value.
- You can search for a specific register: right-click on a register and from the popup menu select **Find Register...** Enter a group or register name filter, click the register you want to see and click **OK**. The register of your interest will be shown in the view.

7.4.12. Trace View

If tracing is enabled, the Trace view shows the code was most recently executed. For example, while you step through the application, the Trace view shows the executed code of each step. To enable tracing:

- Right-click in the Trace view and select **Trace**.

A check mark appears when tracing is enabled.

The view has three tabs, **Source**, **Instruction** and **Raw**, each of which represents the trace in a different way. However, not all target environments will support all three of these. The view is updated automatically each time the target halts.

Chapter 8. Tool Options

This chapter provides a detailed description of the options for the C compiler, assembler, linker, control program, make utility, archiver and the HLL object dumper.

Tool options in Eclipse (Menu entry)

For each tool option that you can set from within Eclipse, a **Menu entry** description is available. In Eclipse you can customize the tools and tool options in the following dialog:

1. From the **Project** menu, select **Properties**

The Properties dialog appears.

2. In the left pane, expand **C/C++ Build** and select **Settings**.

In the right pane the Settings appear.

3. Open the **Tool Settings** tab.

You can set all tool options here.

Unless stated otherwise, all **Menu entry** descriptions expect that you have this Tool Settings tab open.

The following tables give an overview of all tool options on the Tool Settings tab in Eclipse with hyperlinks to the corresponding command line options (if available).

Global Options

Eclipse option	Description or option
Use global 'product directory' preference	Directory where the TASKING toolset is installed
Treat warnings as errors	Control program option --warnings-as-errors
Keep temporary files	Control program option --keep-temporary-files (-t)
Verbose mode of control program	Control program option --verbose (-v)
Endianness	Control program option --endianness
Initialization mode	Control program option --meminit

C Compiler

Eclipse option	Description or option
Preprocessing	

Eclipse option	Description or option
Automatic inclusion of '.sfr' file	C compiler option --include-file
Store preprocessor output in <file>.pre	Control program option --preprocess (-E) / --no-preprocessing-only
Keep comments in preprocessor output	Control program option --preprocess=+comments
Keep #line info in preprocessor output	Control program option --preprocess=-noline
Defined symbols	C compiler option --define
Pre-include files	C compiler option --include-file
Include Paths	
Include paths	C compiler option --include-directory
Language	
Comply to C standard	C compiler option --iso
Allow GNU C extensions	C compiler option --language=+gcc
Allow // comments in ISO C90 mode	C compiler option --language=+comments
Check assignment of string literal to non-const string pointer	C compiler option --language=-strings
Treat 'char' variables as unsigned	C compiler option --uchar
Treat 'int' bit-fields as signed	C compiler option --signed-bitfields
Allow optimization across volatile access	C compiler option --language=-volatile
Allow Shift JIS Kanji in strings	C compiler option --language=+kanji
Floating-Point	
Floating-point model	Control program option --fp-model
Code Generation	
Use extended register set	C compiler option --extended-registers
Allow the use of divide/modulo instructions	C compiler option --instruction-set=+divide
Allow the use of multiply instructions	C compiler option --instruction-set=+multiply
Allocation	
Rename sections	C compiler option --rename-sections
Optimization	
Optimization level	C compiler option --optimize
Trade-off between speed and size	C compiler option --tradeoff
Always inline function calls	C compiler option --inline
Maximum size increment when inlining (in %)	C compiler option --inline-max-incr
Maximum size for functions to always inline	C compiler option --inline-max-size
Custom Optimization	C compiler option --optimize

Eclipse option	Description or option
Debugging	
Generate symbolic debug information	C compiler option --debug-info
Generate control flow information	C compiler option --control-flow-info
MISRA C	
MISRA C checking	C compiler option --misrac
MISRA C version	C compiler option --misrac-version
Warnings instead of errors for mandatory rules	C compiler option --misrac-mandatory-warnings
Warnings instead of errors for required rules	C compiler option --misrac-required-warnings
Warnings instead of errors for advisory rules	C compiler option --misrac-advisory-warnings
Custom 1998 / Custom 2004 / Custom 2012	C compiler option --misrac
CERT C Secure Coding	
CERT C secure code checking	C compiler option --cert
Warnings instead of errors	C compiler option --warnings-as-errors
Custom CERT C	C compiler option --cert
Diagnostics	
Suppress C compiler warnings	C compiler option --no-warnings=num
Suppress all warnings	C compiler option --no-warnings
Perform global type checking on C code	C compiler option --global-type-checking
Maximum number of emitted errors	C compiler option --error-limit
Miscellaneous	
Merge C source code with generated assembly	C compiler option --source
Additional options	C compiler options, Control program options

Assembler

Eclipse option	Description or option
Preprocessing	
Use TASKING preprocessor	Assembler option --preprocessor-type
Automatic inclusion of '.def' file	Assembler option --include-file
Defined symbols	Assembler option --define
Pre-include files	Assembler option --include-file
Include Paths	
Include paths	Assembler option --include-directory

Eclipse option	Description or option
Symbols	
Generate symbolic debug	Assembler option <code>--debug-info</code>
Case insensitive identifiers	Assembler option <code>--case-insensitive</code>
Emit local EQU symbols	Assembler option <code>--emit-locals=+equ</code>
Emit local non-EQU symbols	Assembler option <code>--emit-locals=+symbols</code>
Set default symbol scope to global	Assembler option <code>--symbol-scope</code>
List File	
Generate list file	Control program option <code>--list-files</code>
List ...	Assembler option <code>--list-format</code>
List section summary	Assembler option <code>--section-info=+list</code>
Diagnostics	
Suppress warnings	Assembler option <code>--no-warnings=num</code>
Suppress all warnings	Assembler option <code>--no-warnings</code>
Display section summary	Assembler option <code>--section-info=+console</code>
Maximum number of emitted errors	Assembler option <code>--error-limit</code>
Miscellaneous	
Merge sections with the same name	Assembler option <code>--concatenate-sections</code>
Allow Shift JIS Kanji in strings	Assembler option <code>--kanji</code>
Additional options	Assembler options

Linker

Eclipse option	Description or option
Output Format	
Generate Intel Hex format file	Linker option <code>--output=file:IHEX</code>
Generate S-records file	Linker option <code>--output=file:SREC</code>
Generate C-array file	Linker option <code>--chip-output=basename:CARR:32</code>
Create file for each memory chip	Linker option <code>--chip-output</code>
Size of addresses (in bytes) for Intel Hex records	Linker option <code>--output=file:IHEX:size</code>
Size of addresses (in bytes) for Motorola S records	Linker option <code>--output=file:SREC:size</code>
Emit start address record	Linker option <code>--hex-format=s</code>
Emit list of exported symbols	Linker option <code>--hex-format=y</code>
Libraries	
Rescan libraries to solve unresolved externals	Linker option <code>--no-rescan</code>

Eclipse option	Description or option
Libraries	The libraries are added as files on the command line.
Library search path	Linker option --library-directory
Data Objects	
Data objects	Linker option --import-object
Script File	
Defined symbols	Linker option --define
Linker script file (.lsl)	Linker option --lsl-file
Optimization	
Delete unreferenced sections	Linker option --optimize=c
Use a 'first-fit decreasing' algorithm	Linker option --optimize=l
Compress copy table	Linker option --optimize=t
Delete duplicate code	Linker option --optimize=x
Delete duplicate data	Linker option --optimize=y
Map File	
Generate map file (.map)	Control program option --no-map-file
Generate XML map file format (.mapxml) for map file viewer	Linker option --map-file=file.mapxml:XML
Include ...	Linker option --map-file-format
Diagnostics	
Suppress warnings	Linker option --no-warnings=num
Suppress all warnings	Linker option --no-warnings
Maximum number of emitted errors	Linker option --error-limit
Miscellaneous	
Strip symbolic debug information	Linker option --strip-debug
Link case insensitive	Linker option --case-insensitive
Do not use standard copy table for initialization	Linker option --user-provided-initialization-code
Additional options	Linker options

8.1. C Compiler Options

This section lists all C compiler options.

Options in Eclipse versus options on the command line

Most command line options have an equivalent option in Eclipse but some options are only available on the command line. Eclipse invokes the compiler via the control program. Therefore, it uses the syntax of the control program to pass options and files to the C compiler. If there is no equivalent option in Eclipse, you can specify a command line option in Eclipse as follows:

1. From the **Project** menu, select **Properties for**

The Properties dialog appears.

2. In the left pane, expand **C/C++ Build** and select **Settings**.

In the right pane the Settings appear.

3. On the Tool Settings tab, select **C Compiler » Miscellaneous**.

4. In the **Additional options** field, enter one or more command line options.

*Because Eclipse uses the control program, you have to precede the option with **-Wc** to pass the option via the control program directly to the C compiler.*

Be aware that some command line options are not useful in Eclipse or just do not have any effect. For example, the option **-n** sends output to stdout instead of a file and has no effect in Eclipse.

Short and long option names

Options can have both short and long names. Short option names always begin with a single minus (-) character, long option names always begin with two minus (--) characters. You can abbreviate long option names as long as it forms a unique name. You can mix short and long option names on the command line.

Options can have flags or suboptions. To switch a flag 'on', use a lowercase letter or a **+longflag**. To switch a flag off, use an uppercase letter or a **-longflag**. Separate **longflags** with commas. The following two invocations are equivalent:

```
cmcs -Oac test.c
cmcs --optimize=+coalesce,+cse test.c
```

When you do not specify an option, a default value may become active.

C compiler option: `--cert`

Menu entry

1. Select **C Compiler » CERT C Secure Coding**.
2. Make a selection from the **CERT C secure code checking** list.
3. If you selected **Custom**, expand the **Custom CERT C** entry and enable one or more individual recommendations/rules.

Command line syntax

```
--cert={all | name [-name] , ... }
```

Default format: all

Description

With this option you can enable one or more checks for CERT C Secure Coding Standard recommendations/rules. When you omit the argument, all checks are enabled. *name* is the name of a CERT recommendation/rule, consisting of three letters and two digits. Specify only the three-letter mnemonic to select a whole category. For the list of names you can use, see [Chapter 15, CERT C Secure Coding Standard](#).

On the command line you can use `--diag=cert` to see a list of the available checks, or you can use a three-letter mnemonic to list only the checks in a particular category. For example, `--diag=pre` lists all supported preprocessor checks.

Example

To enable the check for CERT rule STR30-C, enter:

```
cmcs --cert=str30 test.c
```

Related information

[Chapter 15, CERT C Secure Coding Standard](#)

[C compiler option `--diag`](#) (Explanation of diagnostic messages)

C compiler option: --check

Menu entry

-

Command line syntax

`--check`

Description

With this option you can check the source code for syntax errors, without generating code. This saves time in developing your application because the code will not actually be compiled.

The compiler reports any warnings and/or errors.

This option is available on the command line only.

Related information

Assembler option `--check` (Check syntax)

C compiler option: `--control-flow-info`

Menu entry

1. Select **C Compiler » Debugging**.
2. Enable the option **Generate control flow information**.

Command line syntax

```
--control-flow-info
```

Description

With this option the compiler adds control flow information to the output file. The compiler generates a `.debug_control_flow` section which describes the basic blocks and their relations. This information can be used for code coverage analysis on optimized code.

Example

```
cmcs --control-flow-info test.c
```

Related information

Section 6.4.2, *HLL Dump Output Format*

C compiler option `--debug-info` (Debug information)

C compiler option: `--core`

Menu entry

1. Expand **C/C++ Build** and select **Processor**.
2. From the **Processor Selection** list, select a processor or select **User defined ...**.

Command line syntax

`--core=core`

You can specify the following *core* arguments:

mcs3.0	MCS v3.0 core
mcs3.1	MCS v3.1 core

Default: **mcs3.1**

Description

With this option you specify the core architecture for a target processor for which you create your application. If you use Eclipse or the control program, the MCS toolset derives the core from the processor you selected. When the default core (**mcs3.1**) is used, the macro `__CORE_MCS31__` is defined in the C source file.

With `--core=mcs3.0`, the compiler can generate MCS v3.0 instructions in the assembly file. The macro `__CORE_MCS30__` is defined in the C source file.

With `--core=mcs3.1`, the compiler can generate MCS v3.1 instructions in the assembly file. The macro `__CORE_MCS31__` is defined in the C source file.

Example

Select an MCS v3.0 core:

```
cmcs --core=mcs3.0 test.c
```

Related information

Control program option `--cpu` (Select processor)

C compiler option: `--debug-info (-g)`

Menu entry

1. Select **C Compiler » Debugging**.
2. To **generate symbolic debug information**, select **Default**, **Small set** or **Full**.
To disable the generation of debug information, select **None**.

Command line syntax

```
--debug-info[=suboption]
```

```
-g[suboption]
```

You can set the following suboptions:

small	1 / c	Emit small set of debug information.
default	2 / d	Emit default symbolic debug information.
all	3 / a	Emit full symbolic debug information.

Default: `--debug-info` (same as `--debug-info=default`)

Description

With this option you tell the compiler to add directives to the output file for including symbolic information. This facilitates high level debugging but increases the size of the resulting assembler file (and thus the size of the object file). For the final application, compile your C files without debug information.

The DWARF debug format allows for a flexible approach as to how much symbolic information is included, as long as the structure is valid. Adding all possible DWARF data for a program is not practical. The amount of DWARF information per compilation unit can be huge. And for large projects, with many object modules the link time can grow unacceptably long. That is why the compiler has several debug information levels. In general terms one can say, the higher the level the more DWARF information is produced.

The DWARF data in an object module is not only used for debugging. The toolset can also do "type checking" of the whole application. In that case the linker will use the DWARF information of all object modules to determine if every use of a symbol is done with the same type. In other words, if the application is built with type checking enabled then the compiler will add DWARF information too.

Small set of debug information

With this suboption only DWARF call frame information and type information are generated. This enables you to inspect parameters of nested functions. The type information improves debugging. You can perform a stack trace, but stepping is not possible because debug information on function bodies is not generated. You can use this suboption, for example, to compact libraries.

Default debug information

This provides all debug information you need to debug your application. It meets the debugging requirements in most cases without resulting in oversized assembler/object files.

Full debug information

With this suboption extra debug information is generated about unused typedefs and DWARF "lookup table sections". Under normal circumstances this extra debug information is not needed to debug the program. Information about unused typedefs concerns all typedefs, even the ones that are not used for any variable in the program. (Possibly, these unused typedefs are listed in the standard include files.) With this suboption, the resulting assembler/object file will increase significantly.

In the following table you see in more detail what DWARF information is included for the debug option levels.

Feature	-g1	-g2	-g3	type check	Remarks
basic info	+	+	+	+	info such as symbol name and type
call frame	+	+	+	+	this is information for a debugger to compute a stack trace when a program has stopped at a breakpoint
symbol lifetime		+	+		this is information about where symbols live (e.g. on stack at offset so and so, when the program counter is in this range)
line number info		+	+	+	file name, line number, column number
"lookup tables"			+		DWARF sections ... this is an optimization for the DWARF data, it is not essential
unused typedefs			+		in the C code of the program there can be (many) typedefs that are not used for any variable. Sometimes this can cause enormous expansion of the DWARF data and thus it is only included in -g3 .

Related information

-

C compiler option: `--define (-D)`

Menu entry

1. Select **C Compiler » Preprocessing**.

The Defined symbols box shows the symbols that are currently defined.

2. To define a new symbol, click on the **Add** button in the **Defined symbols** box.
3. Type the symbol definition (for example, `demo=1`)

Use the **Edit** and **Delete** button to change a macro definition or to remove a macro from the list.

Command line syntax

```
--define=macro_name[=macro_definition]
```

```
-Dmacro_name[=macro_definition]
```

Description

With this option you can define a macro and specify it to the preprocessor. If you only specify a macro name (no macro definition), the macro expands as '1'.

You can specify as many macros as you like. Simply use the **Add** button to add new macro definitions.

On the command line, you can use the option `--define (-D)` multiple times. If the command line exceeds the limit of the operating system, you can define the macros in an option file which you then must specify to the compiler with the option `--option-file (-f) file`.

Defining macros with this option (instead of in the C source) is, for example, useful to compile conditional C source as shown in the example below.

Make sure you do not use a reserved keyword as a macro name, as this can lead to unexpected results.

Example

Consider the following C program with conditional code to compile a demo program and a real program:

```
void main( void )
{
#if DEMO
    demo_func(); /* compile for the demo program */
#else
    real_func(); /* compile for the real program */
#endif
}
```

TASKING VX-toolset for MCS User Guide

You can now use a macro definition to set the DEMO flag:

```
cmcs --define=DEMO test.c  
cmcs --define=DEMO=1 test.c
```

Note that both invocations have the same effect.

The next example shows how to define a macro with arguments. Note that the macro name and definition are placed between double quotes because otherwise the spaces would indicate a new option.

```
cmcs --define="MAX(A,B)=((A) > (B) ? (A) : (B))" test.c
```

Related information

C compiler option **--undefine** (Remove preprocessor macro)

C compiler option **--option-file** (Specify an option file)

C compiler option: `--dep-file`

Menu entry

Eclipse uses this option in the background to create a file with extension `.d` (one for every input file).

Command line syntax

```
--dep-file[=file]
```

Description

With this option you tell the compiler to generate dependency lines that can be used in a Makefile. In contrast to the option `--preprocess=+make`, the dependency information will be generated in addition to the normal output file.

By default, the information is written to a file with extension `.d` (one for every input file). When you specify a filename, all dependencies will be combined in the specified file.

Example

```
cmcs --dep-file=test.dep test.c
```

The compiler compiles the file `test.c`, which results in the output file `test.src`, and generates dependency lines in the file `test.dep`.

Related information

C compiler option `--preprocess=+make` (Generate dependencies for make)

C compiler option: --diag

Menu entry

1. From the **Window** menu, select **Show View » Other » TASKING » Problems**.

The Problems view is added to the current perspective.

2. In the Problems view right-click on a message.

A popup menu appears.

3. Select **Detailed Diagnostics Info**.

A dialog box appears with additional information.

Command line syntax

```
--diag=[format:]{all | msg[-msg],...}
```

You can set the following output formats:

html	HTML output.
rtf	Rich Text Format.
text	ASCII text.

Default format: text

Description

With this option you can ask for an extended description of error messages in the format you choose. The output is directed to stdout (normally your screen) and in the format you specify. The compiler does not compile any files. You can specify the following formats: **html**, **rtf** or **text** (default). To create a file with the descriptions, you must redirect the output.

With the suboption **all**, the descriptions of all error messages are given (except for the CERT checks). If you want the description of one or more selected error messages, you can specify the error message numbers, separated by commas, or you can specify a range.

With **--diag=cert** you can see a list of the available CERT checks, or you can use a three-letter mnemonic to list only the checks in a particular category. For example, **--diag=pre** lists all supported preprocessor checks.

Example

To display an explanation of message number 282, enter:

```
cmcs --diag=282
```

This results in the following message and explanation:

E282: unterminated comment

Make sure that every comment starting with `/*` has a matching `*/`.
Nested comments are not possible.

To write an explanation of all errors and warnings in HTML format to file `errors.html`, use redirection and enter:

```
cmcs --diag=html:all > errors.html
```

Related information

[Section 3.7, C Compiler Error Messages](#)

[C compiler option `--cert`](#) (Enable individual CERT checks)

C compiler option: --error-file

Menu entry

-

Command line syntax

--error-file[=*file*]

Description

With this option the compiler redirects diagnostic messages to a file. If you do not specify a filename, the error file will be named after the output file with extension `.err`.

Example

To write diagnostic messages to `errors.err` instead of `stderr`, enter:

```
cmcs --error-file=errors.err test.c
```

Related information

-

C compiler option: `--error-limit`

Menu entry

1. Select **C/C++ Compiler » Diagnostics**.
2. Enter a value in the **Maximum number of emitted errors** field.

Command line syntax

```
--error-limit=number
```

Default: 42

Description

With this option you limit the number of error messages in one compiler run to the specified number. When the limit is exceeded, the compiler aborts with fatal error message F105. Warnings and informational messages are not included in the count. When 0 (zero) or a negative number is specified, the compiler emits all errors. Without this option the maximum number of errors is 42.

Related information

[Section 3.7, C Compiler Error Messages](#)

C compiler option: --extended-registers

Menu entry

1. Select **C Compiler » Code Generation**.
2. Enable the option **Use extended register set**.

Command line syntax

--extended-registers

Description

The extended register set extends the registers of the current MCS channel with the registers of the next MCS channel. By default the extended register set is disabled. You can use this option to enable the registers RS0..RS7.

Related information

-

C compiler option: `--fp-model`

Menu entry

1. Select **C Compiler » Floating-Point**.
2. Make a selection from the **Floating-point model** list.
3. If you selected **Custom**, enable one or more individual options.

Command line syntax

`--fp-model=flags`

You can set the following flags:

+/-contract	c/C	allow expression contraction
+/-float	f/F	treat 'double' as 'float'
+/-fastlib	l/L	allow less precise library functions
+/-nonan	n/N	allow optimizations to ignore NaN/Inf
+/-rewrite	r/R	allow expression rewriting
+/-trap	t/T	support trapping on exceptions
+/-negzero	z/Z	ignore sign of -0.0
	0	alias for <code>--fp-model=CFLNRtZ</code> (strict)
	1	alias for <code>--fp-model=cFLNRTZ</code> (precise)
	2	alias for <code>--fp-model=cFlnrTz</code> (fast double)
	3	alias for <code>--fp-model=cflnrTz</code> (fast single)

Default: `--fp-model=cFlnrTz`

Description

With this option you select the floating-point execution model.

With `--fp-model=+contract` you allow the compiler to contract multiple float operations into a single operation, with different rounding results. A possible example is fused multiply-add. With `--fp-model=-contract`, the fused multiply-and-accumulate (FMA) operations are not generated. FMA operations are not supported by the IEEE-754 standard. The result of FMA operations is only rounded once at the end of the FMA.

With `--fp-model=+float` you tell the compiler to treat variables and constants of type `double` as `float`. Because the `float` type takes less space, execution speed increases and code size decreases, both at the cost of less precision. Make sure you specify the corresponding libraries to the linker.

TASKING VX-toolset for MCS User Guide

With **--fp-model=+fastlib** you allow the compiler to select faster but less accurate library functions for certain floating-point operations. With **--fp-model=-fastlib** more precise library functions are used and the compiler defines the macro `__PRECISE_LIB_FP__`, which is used in `math.h`.

With **--fp-model=+nonan** you allow the compiler to ignore NaN or Inf input values. An example is to replace multiply by zero with zero.

With **--fp-model=+rewrite** you allow the compiler to rewrite expressions by reassociating. This might result in rounding differences and possibly different exceptions. An example is to rewrite $(a*c)+(b*c)$ as $(a+b)*c$.

With **--fp-model=+trap** operations trap on floating-point exceptions. The floating-point instructions, as implemented in the FPU, need to be handled in a special way if floating-point trapping behavior is expected from the generated code. Make sure you specify the corresponding trapping floating-point library to the linker.

With **--fp-model=+negzero** you allow the compiler to ignore the sign of -0.0 values. An example is to replace $(a-a)$ by zero.

Related information

Pragmas `STDC_FP_CONTRACT`, `fp_negzero`, `fp_nonan` and `fp_rewrite` in [Section 1.7, Pragmas to Control the Compiler](#).

C compiler option: --global-type-checking

Menu entry

1. Select **C Compiler » Diagnostics**.
2. Enable the option **Perform global type checking on C code**.

Command line syntax

`--global-type-checking`

Description

The C compiler already performs type checking within each module. Use this option when you want the linker to perform type checking between modules.

Related information

-

C compiler option: --help (-?)

Menu entry

-

Command line syntax

`--help[=item]`

`-?`

You can specify the following arguments:

intrinsic s	i	Show the list of intrinsic functions
option s	o	Show extended option descriptions
pragma s	p	Show the list of supported pragmas
typedef s	t	Show the list of predefined typedefs

Description

Displays an overview of all command line options. With an argument you can specify which extended information is shown.

Example

The following invocations all display a list of the available command line options:

```
cmcs -?  
cmcs --help  
cmcs
```

The following invocation displays a list of the available pragmas:

```
cmcs --help=pragmas
```

Related information

-

C compiler option: --include-directory (-I)

Menu entry

1. Select **C Compiler » Include Paths**.

The Include paths box shows the directories that are added to the search path for include files.

2. To define a new directory for the search path, click on the **Add** button in the **Include paths** box.
3. Type or select a path.

Use the **Edit** and **Delete** button to change a path or to remove a path from the list.

Command line syntax

```
--include-directory=path,...
```

```
-Ipath,...
```

Description

With this option you can specify the path where your include files are located. A relative path will be relative to the current directory,

The order in which the compiler searches for include files is:

1. The pathname in the C source file and the directory of the C source (only for #include files that are enclosed in "")
2. The path that is specified with this option.
3. The path that is specified in the environment variable `CMCSINC` when the product was installed.
4. The default directory `$(PRODDIR)\include` (unless you specified option `--no-stdinc`).

Example

Suppose that the C source file `test.c` contains the following lines:

```
#include <stdio.h>
#include "myinc.h"
```

You can call the compiler as follows:

```
cmcs --include-directory=myinclude test.c
```

First the compiler looks for the file `stdio.h` in the directory `myinclude` relative to the current directory. If it was not found, the compiler searches in the environment variable and then in the default include directory.

TASKING VX-toolset for MCS User Guide

The compiler now looks for the file `myinc.h` in the directory where `test.c` is located. If the file is not there the compiler searches in the directory `myinclude`. If it was still not found, the compiler searches in the environment variable and then in the default include directory.

Related information

C compiler option **--include-file** (Include file at the start of a compilation)

C compiler option **--no-stdinc** (Skip standard include files directory)

C compiler option: `--include-file (-H)`

Menu entry

1. Select **C Compiler » Preprocessing**.

The Pre-include files box shows the files that are currently included before the compilation starts.

2. To define a new file, click on the **Add** button in the **Pre-include files** box.
3. Type the full path and file name or select a file.

Use the **Edit** and **Delete** button to change a file name or to remove a file from the list.

Command line syntax

```
--include-file=file,...
```

```
-Hfile,...
```

Description

With this option you include one or more extra files at the beginning of each C source file, before other includes. This is the same as specifying `#include "file"` at the beginning of *each* of your C sources.

Example

```
cmcs --include-file=stdio.h test1.c test2.c
```

The file `stdio.h` is included at the beginning of both `test1.c` and `test2.c`.

Related information

C compiler option `--include-directory` (Add directory to include file search path)

C compiler option: `--inline`

Menu entry

1. Select **C Compiler » Optimization**.
2. Enable the option **Always inline function calls**.

Command line syntax

`--inline`

Description

With this option you instruct the compiler to inline calls to functions without the `__noinline` function qualifier whenever possible. This option has the same effect as a `#pragma inline` at the start of the source file.

Example

To always inline function calls:

```
cmcs --inline test.c
```

Related information

[Section 1.9.5, *Inlining Functions: inline*](#)

C compiler option: `--inline-max-incr` / `--inline-max-size`

Menu entry

1. Select **C Compiler » Optimization**.
2. In the **Maximum size increment when inlining** field, enter a value (default -1).
3. In the **Maximum size for functions to always inline** field, enter a value (default -1).

Command line syntax

```
--inline-max-incr=percentage (default: -1)  
--inline-max-size=threshold (default: -1)
```

Description

With these options you can control the automatic function inlining optimization process of the compiler. These options only have effect when you have enabled the inlining optimization (option `--optimize=+inline` or **Optimize most**).

Regardless of the optimization process, the compiler always inlines all functions that have the function qualifier `inline`.

With the option `--inline-max-size` you can specify the maximum size of functions that the compiler inlines as part of the optimization process. The compiler always inlines all functions that are smaller than the specified *threshold*. The threshold is measured in compiler internal units and the compiler uses this measure to decide which functions are small enough to inline. The default threshold is -1, which means that the threshold depends on the option `--tradeoff`.

After the compiler has inlined all functions that have the function qualifier `inline` and all functions that are smaller than the specified threshold, the compiler looks whether it can inline more functions without increasing the code size too much. With the option `--inline-max-incr` you can specify how much the code size is allowed to increase. The default value is -1, which means that the value depends on the option `--tradeoff`.

Example

```
cmcs --optimize=+inline --inline-max-incr=40 --inline-max-size=15 test.c
```

The compiler first inlines all functions with the function qualifier `inline` and all functions that are smaller than the specified threshold of 15. If the code size has still not increased with 40%, the compiler decides which other functions it can inline.

Related information

C compiler option `--optimize=+inline` (Optimization: automatic function inlining)

Section 1.9.5, *Inlining Functions: inline*

Section 3.5.3, *Optimize for Code Size or Execution Speed*

C compiler option: `--instruction-set`

Menu entry

1. Select **C Compiler » Code Generation**.
2. Enable or disable the option **Allow the use of divide/modulo instructions**.
3. Enable or disable the option **Allow the use of multiply instructions**.

Command line syntax

`--instruction-set=flags`

You can set the following flags:

+/-divide	d/D	allow the use of divide/modulo instructions
+/-multiply	m/M	allow the use of multiply instructions

Default: `--instruction-set=dm`

Description

With this option you can select which instructions the compiler can use for code generation. When the compiler is not allowed to use an instruction a run-time library call is used instead. When the selected core forbids the use of an instruction it will never be used, even when enabled by this option.

With `--instruction-set=+divide` you allow the compiler to use the DIVU and DIVS instructions. These instructions are used to generate code for the divide (/) and modulo (%) operations.

With `--instruction-set=+multiply` you allow the compiler to use the MULU and MULS instructions.

Related information

-

C compiler option: `--iso (-c)`

Menu entry

1. Select **C Compiler » Language**.
2. From the **Comply to C standard** list, select **ISO C99, ISO C11, or ISO C90**.

Command line syntax

```
--iso={90 | 99 | 11}
```

```
-c{90 | 99 | 11}
```

Default: `--iso=11`

Description

With this option you select the ISO C standard. C90 is also referred to as the "ANSI C standard". C99 refers to the ISO/IEC 9899:1999 (E) standard. C11 refers to the ISO/IEC 9899:2011 (E) standard. C11 is the default.

Example

To select the ISO C99 standard on the command line:

```
cmcs --iso=99 test.c
```

Related information

C compiler option `--language` (Language extensions)

C compiler option: **--keep-output-files (-k)**

Menu entry

Eclipse *always* removes the `.src` file when errors occur during compilation.

Command line syntax

`--keep-output-files`

`-k`

Description

If an error occurs during compilation, the resulting `.src` file may be incomplete or incorrect. With this option you keep the generated output file (`.src`) when an error occurs.

By default the compiler removes the generated output file (`.src`) when an error occurs. This is useful when you use the make utility. If the erroneous files are not removed, the make utility may process corrupt files on a subsequent invocation.

Use this option when you still want to inspect the generated assembly source. Even if it is incomplete or incorrect.

Example

```
cmcs --keep-output-files test.c
```

When an error occurs during compilation, the generated output file `test.src` will *not* be removed.

Related information

C compiler option **--warnings-as-errors** (Treat warnings as errors)

C compiler option: `--language (-A)`

Menu entry

1. Select **C Compiler » Language**.
2. Enable or disable one or more of the following options:
 - Allow GNU C extensions
 - Allow `//` comments in ISO C90 mode
 - Check assignment of string literal to non-'const' string pointer
 - Allow optimization across volatile access
 - Allow Shift JIS Kanji in strings

Command line syntax

`--language=[flags]`

`-A[flags]`

You can set the following flags:

+/-gcc	g/G	enable a number of gcc extensions
+/-kanji	k/K	support for Shift JIS Kanji in strings
+/-comments	p/P	<code>//</code> comments in ISO C90 mode
+/-volatile	v/V	don't optimize across volatile access
+/-strings	x/X	relaxed const check for string literals

Default: `-AGKpVx`

Default (without flags): `-AGKPVX`

Description

With this option you control the language extensions the compiler can accept. By default the MCS compiler allows all language extensions, except for **gcc** extensions.

The option `--language (-A)` without flags disables all language extensions.

GNU C extensions

The `--language=+gcc (-Ag)` option enables the following gcc language extensions:

- The identifier `__FUNCTION__` expands to the current function name.
- Alternative syntax for variadic macros.

TASKING VX-toolset for MCS User Guide

- Alternative syntax for designated initializers.
- Allow zero sized arrays.
- Allow empty struct/union.
- Allow unnamed struct/union fields.
- Allow empty initializer list.
- Allow initialization of static objects by compound literals.
- The middle operand of a `? :` operator may be omitted.
- Allow a compound statement inside braces as expression.
- Allow arithmetic on void pointers and function pointers.
- Allow a range of values after a single case label.
- Additional preprocessor directive `#warning`.
- Allow comma operator, conditional operator and cast as lvalue.
- An inline function without "static" or "extern" will be global.
- An "extern inline" function will not be compiled on its own.

For a more complete description of these extensions, you can refer to the UNIX gcc info pages ([info gcc](#)).

Shift JIS Kanji support

With `--language=+kanji (-Ak)` you tell the compiler to support Shift JIS encoded Kanji multi-byte characters in strings, (wide) character constants and `//` comments. Without this option, encodings with 0x5c as the second byte conflict with the use of the backslash as an escape character. Shift JIS in `/* . . . */` comments is supported regardless of this option. Note that Shift JIS also includes Katakana and Hiragana.

Comments in ISO C90 mode

With `--language=+comments (-Ap)` you tell the compiler to allow C++ style comments (`//`) in ISO C90 mode (option `--iso=90`). In ISO C99 mode this style of comments is always accepted.

Check assignment of string literal to non-const string pointer

With `--language=+strings (-Ax)` you disable warnings about discarded `const` qualifiers when a string literal is assigned to a non-`const` pointer.

```
char *p;
int main( void )
{
    p = "hello"; // with -AX the compiler issues warning W525
```

```

    return 0;
}

```

Optimization across volatile access

With the **--language=+volatile (-Av)** option, the compiler will block optimizations when reading or writing a volatile object, by executing all memory and register accesses before the access of the volatile object. The volatile access acts as a memory barrier. With this option you can prevent for example that code below the volatile object is optimized away to somewhere above the volatile object.

Example:

```

extern unsigned int variable;
extern volatile unsigned int access;

void TestFunc( unsigned int flag )
{
    access = 0;
    variable |= flag;
    if( variable == 3 )
    {
        variable = 0;
    }
    variable |= 0x8000;
    access = 1;
}

```

Result with **--language=-volatile** (default):

```

TestFunc:    .type    func
            movl    r5,#0
            mwr    r5,access    ; <== Volatile access
            mrd    r5,variable
            or     r5,r2
            atul   r5,#3
            jbc   sta,#5,.L2
            movl   r5,#0
.L2:
            orl    r5,#32768
            movl   r4,#1
            mwr    r4,access    ; <== Volatile access
            mwr    r5,variable  ; <== Moved across volatile access
            ret

```

Result with **--language=+volatile**:

```

TestFunc:    .type    func
            movl   r5,#0
            mwr    r5,access    ; <== Volatile access
            mrd    r5,variable
            or     r5,r2

```

TASKING VX-toolset for MCS User Guide

```
    atul    r5,#3
    jbc     sta,#5,.L2
    movl    r5,#0
.L2:
    orl     r5,#32768
    mwr     r5,variable    ; <== Not moved
    movl    r5,#1
    mwr     r5,access      ; <== Volatile access
    ret
```

Note that the volatile behavior of the compiler with option **--language=-volatile** or **--language=+volatile** is ISO C compliant in both cases.

Related information

[C compiler option --iso](#) (ISO C standard)

[Section 1.4, Shift JIS Kanji Support](#)

C compiler option: `--make-target`

Menu entry

-

Command line syntax

`--make-target=name`

Description

With this option you can overrule the default target name in the make dependencies generated by the options `--preprocess=+make` (`-Em`) and `--dep-file`. The default target name is the basename of the input file, with extension `.o`.

Example

```
cmcs --preprocess=+make --make-target=mytarget.o test.c
```

The compiler generates dependency lines with the default target name `mytarget.o` instead of `test.o`.

Related information

C compiler option `--preprocess=+make` (Generate dependencies for make)

C compiler option `--dep-file` (Generate dependencies in a file)

C compiler option: `--misrac`

Menu entry

1. Select **C Compiler » MISRA C**.
2. Make a selection from the **MISRA C checking** list.
3. If you selected **Custom**, expand the **Custom 1998**, **Custom 2004** or **Custom 2012** entry and enable one or more individual rules.

Command line syntax

```
--misrac={all | nr[-nr]},...
```

Description

With this option you specify to the compiler which MISRA C rules must be checked. With the option `--misrac=all` the compiler checks for all supported MISRA C rules.

Example

```
cmcs --misrac=9-13 test.c
```

The compiler generates an error for each MISRA C rule 9, 10, 11, 12 or 13 violation in file `test.c`.

Related information

Section 3.6.2, *C Code Checking: MISRA C*

C compiler option `--misrac-mandatory-warnings`

C compiler option `--misrac-advisory-warnings`

C compiler option `--misrac-required-warnings`

Linker option `--misrac-report`

C compiler option: `--misrac-advisory-warnings` / `--misrac-required-warnings` / `--misrac-mandatory-warnings`

Menu entry

1. Select **C Compiler » MISRA C**.
2. Make a selection from the **MISRA C checking** list.
3. Enable one or more of the options:
 - Warnings instead of errors for mandatory rules**
 - Warnings instead of errors for required rules**
 - Warnings instead of errors for advisory rules.**

Command line syntax

```
--misrac-advisory-warnings  
--misrac-required-warnings  
--misrac-mandatory-warnings
```

Description

Normally, if an advisory rule or required rule is violated, the compiler generates an error. As a consequence, no output file is generated. With this option, the compiler generates a warning instead of an error.

Related information

Section 3.6.2, *C Code Checking: MISRA C*

C compiler option `--misrac`

Linker option `--misrac-report`

C compiler option: --misrac-version

Menu entry

1. Select **C Compiler » MISRA C**.
2. Select the **MISRA C version: 1998, 2004 or 2012**.

Command line syntax

`--misrac-version={1998 | 2004 | 2012}`

Default: 2004

Description

MISRA C rules exist in three versions: MISRA C:1998, MISRA C:2004 and MISRA C:2012. By default, the C source is checked against the MISRA C:2004 rules. With this option you can select which version to use.

Related information

Section 3.6.2, *C Code Checking: MISRA C*

C compiler option `--misrac`

C compiler option: `--no-stdinc`

Menu entry

1. Select **C Compiler » Miscellaneous**.
2. Add the option `--no-stdinc` to the **Additional options** field.

Command line syntax

`--no-stdinc`

Description

With this option you tell the compiler not to look in the default `include` directory relative to the installation directory, when searching for include files. This way the compiler only searches in the include file search paths you specified.

Related information

C compiler option `--include-directory` (Add directory to include file search path)

Section 3.3, *How the Compiler Searches Include Files*

C compiler option: `--no-warnings (-w)`

Menu entry

1. Select **C Compiler » Diagnostics**.

The Suppress C compiler warnings box shows the warnings that are currently suppressed.

2. To suppress a warning, click on the **Add** button in the **Suppress C compiler warnings** box.
3. Enter the numbers, separated by commas or as a range, of the warnings you want to suppress (for example 537, 538). Or you can use the **Add** button multiple times.
4. To suppress all warnings, enable the option **Suppress all warnings**.

Use the **Edit** and **Delete** button to change a warning number or to remove a number from the list.

Command line syntax

```
--no-warnings[=number[-number],...]
```

```
-w[number[-number],...]
```

Description

With this option you can suppresses all warning messages or specific warning messages.

On the command line this option works as follows:

- If you do not specify this option, all warnings are reported.
- If you specify this option but without numbers, all warnings are suppressed.
- If you specify this option with a number or a range, only the specified warnings are suppressed. You can specify the option `--no-warnings=number` multiple times.

Example

To suppress warnings 537 and 538, enter:

```
cmcs test.c --no-warnings=537,538
```

Related information

C compiler option `--warnings-as-errors` (Treat warnings as errors)

[Pragma warning](#)

C compiler option: --optimize (-O)

Menu entry

1. Select **C Compiler » Optimization**.
2. Select an optimization level in the **Optimization level** box.

Command line syntax

`--optimize[=flags]`

`-Oflags`

You can set the following flags:

+/-coalesce	a/A	Coalescer: remove unnecessary moves
+/-ipro	b/B	Interprocedural register optimizations
+/-cse	c/C	Common subexpression elimination
+/-expression	e/E	Expression simplification
+/-flow	f/F	Control flow simplification
+/-glo	g/G	Generic assembly code optimizations
+/-wrap	h/H	Shrink wrapping
+/-inline	i/I	Automatic function inlining
+/-loop	l/L	Loop transformations
+/-forward	o/O	Forward store
+/-propagate	p/P	Constant propagation
+/-subscript	s/S	Subscript strength reduction
+/-unroll	u/U	Unroll small loops
+/-peephole	y/Y	Peephole optimizations

Use the following options for predefined sets of flags:

--optimize=0 **-O0** No optimization
Alias for **-OaBCEFGHILOPSUY**

No optimizations are performed except for the coalescer (to allow better debug information). The compiler tries to achieve an optimal resemblance between source code and produced code. Expressions are evaluated in the same order as written in the source code, associative and commutative properties are not used.

--optimize=1 **-O1** Optimize
Alias for **-OabcefghILOPSUy**

Enables optimizations that do not affect the debug ability of the source code. Use this level when you encounter problems during debugging your source code with optimization level 2.

--optimize=2 **-O2** Optimize more (default)
Alias for **-OabcefgHllopsUy**

Enables more optimizations to reduce code size and/or execution time. This is the default optimization level.

--optimize=3 **-O3** Optimize most
Alias for **-OabcefgHilopsuy**

This is the highest optimization level. Use this level to decrease execution time to meet your real-time requirements.

Default: **--optimize=2**

Description

With this option you can control the level of optimization. If you do not use this option, the default optimization level is *Optimize more* (option **--optimize=2** or **--optimize**).

When you use this option to specify a set of optimizations, you can overrule these settings in your C source file with `#pragma optimize flag/#pragma endoptimize`.

In addition to the option **--optimize**, you can specify the option **--tradeoff (-t)**. With this option you specify whether the used optimizations should optimize for more speed (regardless of code size) or for smaller code size (regardless of speed).

Example

The following invocations are equivalent and result all in the default optimization set:

```
cmcs test.c

cmcs --optimize=2 test.c
cmcs -O2 test.c

cmcs --optimize test.c
cmcs -O test.c

cmcs -OabcefgHllopsy test.c
cmcs --optimize=+coalesce,+ipro,+cse,+expression,+flow,
      +glo,+wrap,-inline,+loop,+forward,+propagate,
      +subscript,-unroll,+peephole test.c
```

Related information

C compiler option **--tradeoff** (Trade off between speed and size)

[Pragma optimize/endoptimize](#)

[Section 3.5, Compiler Optimizations](#)

C compiler option: `--option-file (-f)`

Menu entry

1. Select **C Compiler » Miscellaneous**.
2. Add the option `--option-file` to the **Additional options** field.

Be aware that the options in the option file are added to the C compiler options you have set in the other pages. Only in extraordinary cases you may want to use them in combination.

Command line syntax

```
--option-file=file,...
```

```
-f file,...
```

Description

This option is primarily intended for command line use. Instead of typing all options on the command line, you can create an option file which contains all options and flags you want to specify. With this option you specify the option file to the compiler.

Use an option file when the command line would exceed the limits of the operating system, or just to store options and save typing.

You can specify the option `--option-file` multiple times.

Format of an option file

- Multiple arguments on one line in the option file are allowed.
- To include whitespace in an argument, surround the argument with single or double quotes.
- If you want to use single quotes as part of the argument, surround the argument by double quotes and vice versa:

```
"This has a single quote ' embedded"
```

```
'This has a double quote " embedded'
```

```
'This has a double quote " and a single quote ''' embedded"
```

- When a text line reaches its length limit, use a `\` to continue the line. Whitespace between quotes is preserved.

```
"This is a continuation \  
line"
```

```
-> "This is a continuation line"
```

TASKING VX-toolset for MCS User Guide

- It is possible to nest command line files up to 25 levels.

Example

Suppose the file `myoptions` contains the following lines:

```
--debug-info  
--define=DEMO=1  
test.c
```

Specify the option file to the compiler:

```
cmcs --option-file=myoptions
```

This is equivalent to the following command line:

```
cmcs --debug-info --define=DEMO=1 test.c
```

Related information

-

C compiler option: --output (-o)

Menu entry

Eclipse names the output file always after the C source file.

Command line syntax

```
--output=file
```

```
-o file
```

Description

With this option you can specify another filename for the output file of the compiler. Without this option the basename of the C source file is used with extension `.src`.

Example

To create the file `output.src` instead of `test.src`, enter:

```
cmcs --output=output.src test.c
```

Related information

-

C compiler option: `--preprocess (-E)`

Menu entry

1. Select **C Compiler » Preprocessing**.
2. Enable the option **Store preprocessor output in <file>.pre**.
3. (Optional) Enable the option **Keep comments in preprocessor output**.
4. (Optional) Enable the option **Keep #line info in preprocessor output**.

Command line syntax

`--preprocess [=flags]`

`-E[flags]`

You can set the following flags:

+/-comments	c/C	keep comments
+/-includes	i/I	generate a list of included source files
+/-list	I/L	generate a list of macro definitions
+/-make	m/M	generate dependencies for make
+/-noline	p/P	strip #line source position information

Default: `-ECILMP`

Description

With this option you tell the compiler to preprocess the C source. Under Eclipse the compiler sends the preprocessed output to the file `name.pre` (where `name` is the name of the C source file to compile). Eclipse also compiles the C source.

On the command line, the compiler sends the preprocessed file to stdout. To capture the information in a file, specify an output file with the option `--output`.

With `--preprocess=+comments` you tell the preprocessor to keep the comments from the C source file in the preprocessed output.

With `--preprocess=+includes` the compiler will generate a list of all included source files. The preprocessor output is discarded.

With `--preprocess=+list` the compiler will generate a list of all macro definitions. The preprocessor output is discarded.

With `--preprocess=+make` the compiler will generate dependency lines that can be used in a Makefile. The preprocessor output is discarded. The default target name is the basename of the input file, with the extension `.o`. With the option `--make-target` you can specify a target name which overrules the default target name.

With **--preprocess=+noline** you tell the preprocessor to strip the #line source position information (lines starting with #line). These lines are normally processed by the assembler and not needed in the preprocessed output. When you leave these lines out, the output is easier to read.

Example

```
cmcs --preprocess=+comments,+includes,-list,-make,-noline test.c --output=test.pre
```

The compiler preprocesses the file `test.c` and sends the output to the file `test.pre`. Comments and a list of all included source files are included but no list of macro definitions and no dependencies are generated and the line source position information is not stripped from the output file.

Related information

C compiler option **--dep-file** (Generate dependencies in a file)

C compiler option **--make-target** (Specify target name for **-Em** output)

C compiler option: --rename-sections (-R)

Menu entry

1. Select **C Compiler » Allocation**

The *Rename sections* box shows the sections that are currently renamed.

2. To rename a section, click on the **Add** button in the **Rename sections** box.
3. Type the rename rule in the format *type=format* or *format* (for example, `mcsdata={module}.{attrib}`)

Use the **Edit** and **Delete** button to change a section renaming or to remove an entry from the list.

Command line syntax

```
--rename-sections[=[type=][format_string]],...
```

```
-R[[type=][format_string]],...
```

Default section name: `.type.{module}.{name}`

Description

By default the compiler extends the standard ELF section names with the module name and the name of the symbol that is allocated in the section. You can use this option to create your own unique section names to ease selection in linker script files for locating.

With the *type* argument you select which sections are renamed. When the type of a section matches, the section name will get the specified *format_string* as suffix.

You can specify the following section types:

Section type	Description
mcstext	program code
mcsdata	initialized data
mcsbss	uninitialized data (cleared)
all	all sections

When you omit the type or use type "**all**", all sections will be renamed.

With the *format_string* you specify the string that extends the ELF section name. The format string can contain characters and may contain the following format specifiers:

{attrib}	Expands to the section attributes, separated by underscores. The cluster attribute, used when debug information is enabled, is not included.
{module}	Expands to the basename of the module name.

{name} Expands to the object name, name of variable or function.

In format specifier expansions (for example, a module name with an extra dot), dots ('.') are replaced by dollars (\$).

When you omit the *format_string*, only the section type will be used as the section name.

Example

To rename sections of type `mcsdata` to `.mcsdata.mydata.variable_name`:

```
cmcs --rename-sections=mcsdata=mydata.{name} test.c
```

To generate the section name `.type.NEW` instead of the default section name `.type.module_name.symbol_name`, enter:

```
cmcs -RNEW test.c
```

To generate the section name `section_type_prefix` instead of the default section name `section_type_prefix.module_name.symbol_name`, enter:

```
cmcs -R test.c
```

Related information

[Section 1.10, Section Naming](#)

C compiler option: `--signed-bitfields`

Menu entry

1. Select **C Compiler » Language**.
2. Enable the option **Treat 'int' bit-fields as signed**.

Command line syntax

`--signed-bitfields`

Description

For bit-fields it depends on the implementation whether a plain `int` is treated as `signed int` or `unsigned int`. By default an `int` bit-field is treated as `unsigned int`. This offers the best performance. With this option you tell the compiler to treat `int` bit-fields as `signed int`. In this case, you can still add the keyword `unsigned` to treat a particular `int` bit-field as `unsigned`.

Related information

Section 1.1, *Data Types*

C compiler option: `--source (-s)`

Menu entry

1. Select **C Compiler » Miscellaneous**.
2. Enable the option **Merge C source code with generated assembly**.

Command line syntax

`--source`

`-s`

Description

With this option you tell the compiler to merge C source code with generated assembly code in the output file. The C source lines are included as comments.

Related information

Pragmas [source/nosource](#)

C compiler option: --stdout (-n)

Menu entry

-

Command line syntax

`--stdout`

`-n`

Description

With this option you tell the compiler to send the output to `stdout` (usually your screen). No files are created. This option is for example useful to quickly inspect the output or to redirect the output to other tools.

Related information

-

C compiler option: `--tradeoff (-t)`

Menu entry

1. Select **C Compiler » Optimization**.
2. Select a trade-off level in the **Trade-off between speed and size** box.

Command line syntax

```
--tradeoff={0|1|2|3|4}
```

```
-t{0|1|2|3|4}
```

Default: `--tradeoff=4`

Description

If the compiler uses certain optimizations (option `--optimize`), you can use this option to specify whether the used optimizations should optimize for more speed (regardless of code size) or for smaller code size (regardless of speed).

By default the compiler optimizes for code size (`--tradeoff=4`).

If you have not specified the option `--optimize`, the compiler uses the default *Optimize more* optimization. In this case it is still useful to specify a trade-off level.

With option `--tradeoff=3` or `--tradeoff=4` the loop alignment optimization is switched off.

Example

To set the trade-off level for the used optimizations:

```
cmcs --tradeoff=2 test.c
```

The compiler uses the default *Optimize more* optimization level and balances speed and size while optimizing.

Related information

C compiler option `--optimize` (Specify optimization level)

Section 3.5.3, *Optimize for Code Size or Execution Speed*

C compiler option: --uchar (-u)

Menu entry

1. Select **C Compiler » Language**.
2. Enable the option **Treat 'char' variables as unsigned**.

Command line syntax

--uchar

-u

Description

By default `char` is the same as specifying `signed char`. With this option `char` is the same as `unsigned char`.

Related information

Section 1.1, *Data Types*

C compiler option: `--undefine (-U)`

Menu entry

1. Select **C Compiler » Preprocessing**

The Defined symbols box shows the symbols that are currently defined.

2. To remove a defined symbol, select the symbol in the **Defined symbols** box and click on the **Delete** button.

Command line syntax

`--undefine=macro_name`

`-Umacro_name`

Description

With this option you can undefine an earlier defined macro as with `#undef`. This option is for example useful to undefine predefined macros.

The following predefined ISO C standard macros cannot be undefined:

<code>__FILE__</code>	current source filename
<code>__LINE__</code>	current source line number (int type)
<code>__TIME__</code>	hh:mm:ss
<code>__DATE__</code>	Mmm dd yyyy
<code>__STDC__</code>	level of ANSI standard

Example

To undefine the predefined macro `__TASKING__`:

```
cmcs --undefine=__TASKING__ test.c
```

Related information

C compiler option `--define` (Define preprocessor macro)

Section 1.8, *Predefined Preprocessor Macros*

C compiler option: `--unroll-factor`

Menu entry

-

Command line syntax

`--unroll-factor=value`

Default: `--unroll-factor=-1`

Description

With the loop unrolling optimization, short loops are eliminated by replacing them with a number of copies to reduce the number of branches. With this option you specify how many times eligible loops should be unrolled. When the unroll factor is -1 (default), small loops are unrolled automatically if the loop unrolling optimization (`--optimize=+unroll / -Ou`) is enabled and the optimization trade-off is set for speed (`--tradeoff=0 / -t0`).

Instead of this option you can use the following pragmas:

```
#pragma unroll_factor value
...
#pragma endunroll_factor
```

Example

To allow an unroll factor of four, enter:

```
cmcs --optimize=+unroll --unroll-factor=4 --tradeoff=0 test.c
```

Related information

Pragma `unroll_factor`

C compiler option `--optimize` (Specify optimization level)

C compiler option `--tradeoff` (Trade off between speed and size)

Section 3.5, *Compiler Optimizations*

C compiler option: --verbose (-v)

Menu entry

-

Command line syntax

--verbose

-v

Description

With this option you put the C compiler in verbose mode. The C compiler performs its tasks while it prints the steps it performs to `stdout`.

Related information

-

C compiler option: --version (-V)

Menu entry

-

Command line syntax

`--version`

`-V`

Description

Display version information. The compiler ignores all other options or input files.

Related information

-

C compiler option: `--warnings-as-errors`

Menu entry

1. Select **Global Options**.
2. Enable the option **Treat warnings as errors**.

Command line syntax

```
--warnings-as-errors [=number [-number], ...]
```

Description

If the compiler encounters an error, it stops compiling. When you use this option without arguments, you tell the compiler to treat all warnings not suppressed by option `--no-warnings` (or `#pragma warning`) as errors. This means that the exit status of the compiler will be non-zero after one or more compiler warnings. As a consequence, the compiler now also stops after encountering a warning.

You can limit this option to specific warnings by specifying a comma-separated list of warning numbers or ranges. In this case, this option takes precedence over option `--no-warnings` (and `#pragma warning`).

Related information

[C compiler option `--no-warnings`](#) (Suppress some or all warnings)

[Pragma warning](#)

8.2. Assembler Options

This section lists all assembler options.

Options in Eclipse versus options on the command line

Most command line options have an equivalent option in Eclipse but some options are only available on the command line. Eclipse invokes the assembler via the control program. Therefore, it uses the syntax of the control program to pass options and files to the assembler. If there is no equivalent option in Eclipse, you can specify a command line option in Eclipse as follows:

1. From the **Project** menu, select **Properties for**

The Properties dialog appears.

2. In the left pane, expand **C/C++ Build** and select **Settings**.

In the right pane the Settings appear.

3. On the Tool Settings tab, select **Assembler » Miscellaneous**.

4. In the **Additional options** field, enter one or more command line options.

*Because Eclipse uses the control program, Eclipse automatically precedes the option with **-Wa** to pass the option via the control program directly to the assembler.*

Be aware that some command line options are not useful in Eclipse or just do not have any effect. For example, the option **-V** displays version header information and has no effect in Eclipse.

Short and long option names

Options can have both short and long names. Short option names always begin with a single minus (-) character, long option names always begin with two minus (--) characters. You can abbreviate long option names as long as it forms a unique name. You can mix short and long option names on the command line.

Options can have flags or suboptions. To switch a flag 'on', use a lowercase letter or a **+longflag**. To switch a flag off, use an uppercase letter or a **-longflag**. Separate **longflags** with commas. The following two invocations are equivalent:

```
asmcs -l -LeM test.src
asmcs --list-file --list-format=+symbol,-macro test.src
```

When you do not specify an option, a default value may become active.

Assembler option: `--case-insensitive (-c)`

Menu entry

1. Select **Assembler » Symbols**.
2. Enable the option **Case insensitive identifiers**.

Command line syntax

`--case-insensitive`

`-c`

Default: case sensitive

Description

With this option you tell the assembler not to distinguish between uppercase and lowercase characters. By default the assembler considers uppercase and lowercase characters as different characters.

Example

When assembling case insensitive, the label `LabelName` is the same label as `labelname`.

```
asmcs --case-insensitive test.asm
```

Related information

Assembler control `$CASE`

Assembler option: --check

Menu entry

-

Command line syntax

`--check`

Description

With this option you can check the source code for syntax errors, without generating code. This saves time in developing your application.

The assembler reports any warnings and/or errors.

This option is available on the command line only.

Related information

-

Assembler option: `--concatenate-sections`

Menu entry

1. Select **Assembler » Miscellaneous**.
2. Enable the option **Merge sections with the same name**.

Command line syntax

`--concatenate-sections`

Description

By default the linker does not merge sections with the same name into one section. With this option the assembler uses the section attribute `concat`, instructing the linker to merge sections with the same name.

The advantage of section concatenation is faster locating, because there are less sections to locate.

The disadvantage of section concatenation is less efficient memory use, because of alignment gaps between (sequentially concatenated) sections.

Related information

-

Assembler option: **--core**

Menu entry

1. Expand **C/C++ Build** and select **Processor**.
2. From the **Processor Selection** list, select a processor.

Command line syntax

--core=core

You can specify the following *core* arguments:

mcs1.0	MCS v1.0
mcs2.0	MCS v2.0
mcs3.0	MCS v3.0
mcs3.1	MCS v3.1

Default: **mcs1.0**

Description

With this option you specify the core architecture for a target processor for which you create your application. If you use Eclipse or the control program, the MCS toolset derives the core from the processor you selected. The define `__CORE__` expands to the core argument without the dot. When the default core (**mcs1.0**) is used, the define `__CORE_MCS10__` is set to 1.

With **--core=mcs2.0**, you can use MCS v2.0 instructions in the assembly code. The define `__CORE_MCS20__` is set to 1.

With **--core=mcs3.0**, you can use MCS v3.0 instructions in the assembly code. The define `__CORE_MCS30__` is set to 1.

With **--core=mcs3.1**, you can use MCS v3.1 instructions in the assembly code. The define `__CORE_MCS31__` is set to 1.

Example

To allow the use of MCS v3.1 instructions in the assembly code, enter:

```
asmcs --core=mcs3.1 test.src
```

Related information

Control program option **--cpu** (Select processor)

Assembler option: **--debug-info (-g)**

Menu entry

1. Select **Assembler » Symbols**.
2. Select an option from the **Generate symbolic debug** list.

Command line syntax

`--debug-info[=flags]`

`-g[flags]`

You can set the following flags:

+/-asm	a/A	Assembly source line information
+/-local	I/L	Assembler local symbols debug information

Default: `--debug-info=-asm,-local`

Default (without flags): `--debug-info=+asm,+local`

Description

With this option you tell the assembler which kind of debug information to emit in the object file.

With `--debug-info=+asm` the assembler generates assembly source line information.

With `--debug-info=+local` the assembler generates local symbols debug information.

By default the assembler does not generate any debug information.

Related information

Assembler control **\$DEBUG**

Assembler option: --define (-D)

Menu entry

1. Select **Assembler » Preprocessing**.

The Defined symbols box right-below shows the symbols that are currently defined.

2. To define a new symbol, click on the **Add** button in the **Defined symbols** box.
3. Type the symbol definition (for example, `demo=1`)

Use the **Edit** and **Delete** button to change a macro definition or to remove a macro from the list.

Command line syntax

```
--define=macro_name[=macro_definition]
```

```
-Dmacro_name[=macro_definition]
```

Description

With this option you can define a macro and specify it to the assembler preprocessor. If you only specify a macro name (no macro definition), the macro expands as '1'.

You can specify as many macros as you like. Simply use the **Add** button to add new macro definitions.

On the command line, use the option **--define (-D)** multiple times. If the command line exceeds the limit of the operating system, you can define the macros in an option file which you then must specify to the assembler with the option **--option-file (-f) file**.

Defining macros with this option (instead of in the assembly source) is, for example, useful in combination with conditional assembly as shown in the example below.

This option has the same effect as defining symbols via the `.DEFINE`, `.SET`, and `.EQU` directives (similar to `#define` in the C language). With the `.MACRO` directive you can define more complex macros.

Make sure you do not use a reserved keyword as a macro name, as this can lead to unexpected results.

Example

Consider the following assembly program with conditional code to assemble a demo program and a real program:

```
.IF DEMO == 1
...           ; instructions for demo application
.ELSE
...           ; instructions for the real application
.ENDIF
```

You can now use a macro definition to set the DEMO flag:

```
asmcs --define=DEMO test.asm
asmcs --define=DEMO=1 test.asm
```

Note that both invocations have the same effect.

Related information

Assembler option **--option-file** (Specify an option file)

Assembler option: **--dep-file**

Menu entry

-

Command line syntax

--dep-file[=*file*]

Description

With this option you tell the assembler to generate dependency lines that can be used in a Makefile. The dependency information will be generated in addition to the normal output file.

By default, the information is written to a file with extension `.d`. When you specify a filename, all dependencies will be combined in the specified file.

Example

```
asmcs --dep-file=test.dep test.asm
```

The assembler assembles the file `test.asm`, which results in the output file `test.o`, and generates dependency lines in the file `test.dep`.

Related information

Assembler option **--make-target** (Specify target name for **--dep-file** output)

Assembler option: `--diag`

Menu entry

1. From the **Window** menu, select **Show View » Other » TASKING » Problems**.

The Problems view is added to the current perspective.

2. In the Problems view right-click on a message.

A popup menu appears.

3. Select **Detailed Diagnostics Info**.

A dialog box appears with additional information.

Command line syntax

```
--diag=[format:]{all | nr,...}
```

You can set the following output formats:

html	HTML output.
rtf	Rich Text Format.
text	ASCII text.

Default format: text

Description

With this option you can ask for an extended description of error messages in the format you choose. The output is directed to stdout (normally your screen) and in the format you specify. You can specify the following formats: **html**, **rtf** or **text** (default). To create a file with the descriptions, you must redirect the output.

With the suboption **all**, the descriptions of all error messages are given. If you want the description of one or more selected error messages, you can specify the error message numbers, separated by commas.

Example

To display an explanation of message number 244, enter:

```
asmcs --diag=244
```

This results in the following message and explanation:

```
W244: additional input files will be ignored
```

The assembler supports only a single input file. All other input files are ignored.

TASKING VX-toolset for MCS User Guide

To write an explanation of all errors and warnings in HTML format to file `aserrors.html`, use redirection and enter:

```
asmcs --diag=html:all > aserrors.html
```

Related information

[Section 4.5, *Assembler Error Messages*](#)

Assembler option: `--emit-locals`

Menu entry

1. Select **Assembler » Symbols**.
2. Enable or disable one or both of the following options:
 - Emit local EQU symbols
 - Emit local non-EQU symbols

Command line syntax

`--emit-locals[=flag,...]`

You can set the following flags:

<code>+/-equs</code>	<code>e/E</code>	emit local EQU symbols
<code>+/-symbols</code>	<code>s/S</code>	emit local non-EQU symbols

Default: `--emit-locals=ES`

Default (without flags): `--emit-locals=+symbols`

Description

With the option `--emit-locals=+equs` the assembler also emits local EQU symbols to the object file. Normally, only global symbols and non-EQU local symbols are emitted. Having local symbols in the object file can be useful for debugging.

Related information

Assembler directive [.EQU](#)

Assembler option: **--endianness**

Menu entry

1. Select **Global Options**.
2. Specify the **Endianness:Little-endian mode** or **Big-endian mode**.

Command line syntax

--endianness=*endianness*

-B

--big-endian

You can specify the following *endianness*:

big	b	Big endian
little	l	Little endian (default)

Description

By default, the assembler generates object files with instructions and data in little-endian format (least significant byte of a word at lowest byte address). With **--endianness=big** the assembler generates object files in big-endian format (most significant byte of a word at lowest byte address). **-B** is an alias for option **--endianness=big**.

The endianness is reflected in the list file.

Assembly code can check the setting of this option by means of the built-in assembly function `@BIGENDIAN()`.

Related information

Assembly function `@BIGENDIAN()`

Assembler option: `--error-file`

Menu entry

-

Command line syntax

```
--error-file[=file]
```

Description

With this option the assembler redirects diagnostic messages to a file. If you do not specify a filename, the error file will be named after the output file with extension `.ers`.

Example

To write diagnostic messages to `errors.ers` instead of `stderr`, enter:

```
asmcs --error-file=errors.ers test.asm
```

Related information

[Section 4.5, *Assembler Error Messages*](#)

Assembler option: **--error-limit**

Menu entry

1. Select **Assembler » Diagnostics**.
2. Enter a value in the **Maximum number of emitted errors** field.

Command line syntax

`--error-limit=number`

Default: 42

Description

With this option you tell the assembler to only emit the specified maximum number of errors. When 0 (null) is specified, the assembler emits all errors. Without this option the maximum number of errors is 42.

Related information

Section 4.5, *Assembler Error Messages*

Assembler option: `--extended-registers`

Menu entry

1. Select **C Compiler » Code Generation**.
2. Enable the option **Use extended register set**.

Command line syntax

`--extended-registers`

Description

The extended register set extends the registers of the current MCS channel with the registers of the next MCS channel. These registers are RS0..RS7, DSTAT, GMI0 and GMI1. By default the extended register set is disabled. You can use this option to enable the extended register set.

Related information

-

Assembler option: --help (-?)

Menu entry

-

Command line syntax

`--help[=item]`

`-?`

You can specify the following arguments:

options	Show extended option descriptions
----------------	-----------------------------------

Description

Displays an overview of all command line options. When you specify the argument **options** you can list detailed option descriptions.

Example

The following invocations all display a list of the available command line options:

```
asmcs -?  
asmcs --help  
asmcs
```

To see a detailed description of the available options, enter:

```
asmcs --help=options
```

Related information

-

Assembler option: --include-directory (-I)

Menu entry

1. Select **Assembler » Include Paths**.

The Include paths box shows the directories that are added to the search path for include files.

2. To define a new directory for the search path, click on the **Add** button in the **Include paths** box.
3. Type or select a path.

Use the **Edit** and **Delete** button to change a path or to remove a path from the list.

Command line syntax

```
--include-directory=path,...
```

```
-Ipath,...
```

Description

With this option you can specify the path where your include files are located. A relative path will be relative to the current directory,

The order in which the assembler searches for include files is:

1. The pathname in the assembly file and the directory of the assembly source.
2. The path that is specified with this option.
3. The path that is specified in the environment variable `ASMCSINC` when the product was installed.
4. The default directory `$(PRODDIR)\include`.

Example

Suppose that the assembly source file `test.asm` contains the following lines:

```
.INCLUDE 'myinc.inc'
```

You can call the assembler as follows:

```
asmcs --include-directory=c:\proj\include test.asm
```

First the assembler looks for the file `myinc.inc` in the directory where `test.asm` is located. If it does not find the file, it looks in the directory `c:\proj\include` (this option). If the file is still not found, the assembler searches in the environment variable and then in the default include directory.

Related information

Assembler option **--include-file** (Include file at the start of the input file)

Assembler option: --include-file (-H)

Menu entry

1. Select **Assembler » Preprocessing**.

The Pre-include files box shows the files that are currently included before the assembling starts.

2. To define a new file, click on the **Add** button in the **Pre-include files** box.
3. Type the full path and file name or select a file.

Use the **Edit** and **Delete** button to change a file name or to remove a file from the list.

Command line syntax

```
--include-file=file,...
```

```
-Hfile,...
```

Description

With this option (set at project level) you include one extra file at the beginning of the assembly source file. The specified include file is included before all other includes. This is the same as specifying `.INCLUDE 'file'` at the beginning of your assembly source.

Example

```
asmcs --include-file=myinc.inc test.asm
```

The file `myinc.inc` is included at the beginning of `test.asm` before it is assembled.

Related information

Assembler option [--include-directory](#) (Add directory to include file search path)

Assembler option: `--instruction-set`

Menu entry

1. Select **C Compiler » Code Generation**.
2. Enable or disable the option **Allow divide/modulo instructions**.
3. Enable or disable the option **Allow multiply instructions**.

Command line syntax

`--instruction-set=flags`

You can set the following flags:

+/-divide	d/D	allow the use of divide/modulo instructions
+/-multiply	m/M	allow the use of multiply instructions

Default: `--instruction-set=dm`

Description

With this option you can select which instructions the assembler accepts. When the selected core forbids the use of an instruction it will never be used, even when enabled by this option.

With `--instruction-set=+divide` you allow the assembler to use the DIVU and DIVS instructions.

With `--instruction-set=+multiply` you allow the assembler to use the MULU and MULS instructions.

Related information

-

Assembler option: --kanji

Menu entry

1. Select **Assembler » Miscellaneous**.
2. Enable the option **Allow Shift JIS Kanji in strings**.

Command line syntax

`--kanji`

Description

With this option you tell the assembler to support Shift JIS encoded Kanji multi-byte characters in strings. Without this option, encodings with 0x5c as the second byte conflict with the use of the backslash as an escape character. Shift JIS in comments is supported regardless of this option.

Note that Shift JIS also includes Katakana and Hiragana.

Related information

-

Assembler option: **--keep-output-files (-k)**

Menu entry

Eclipse *always* removes the object file when errors occur during assembling.

Command line syntax

--keep-output-files

-k

Description

If an error occurs during assembling, the resulting object file (.o) may be incomplete or incorrect. With this option you keep the generated object file when an error occurs.

By default the assembler removes the generated object file when an error occurs. This is useful when you use the make utility. If the erroneous files are not removed, the make utility may process corrupt files on a subsequent invocation.

Use this option when you still want to use the generated object. For example when you know that a particular error does not result in a corrupt object file.

Related information

Assembler option **--warnings-as-errors** (Treat warnings as errors)

Assembler option: **--list-file (-l)**

Menu entry

1. Select **Assembler » List File**.
2. Enable the option **Generate list file**.
3. Enable or disable the types of information to be included.

Command line syntax

--list-file[=*file*]

-l[*file*]

Default: no list file is generated

Description

With this option you tell the assembler to generate a list file. A list file shows the generated object code and the relative addresses. Note that the assembler generates a relocatable object file with relative addresses.

With the optional *file* you can specify an alternative name for the list file. By default, the name of the list file is the basename of the output file with the extension `.lst`.

Related information

Assembler option **--list-format** (Format list file)

Assembler option: --list-format (-L)

Menu entry

1. Select **Assembler » List File**.
2. Enable the option **Generate list file**.
3. Enable or disable the types of information to be included.

Command line syntax

`--list-format=flag,...`

`-Lflags`

You can set the following flags:

+/-section	d/D	List section directives (.SDECL, .SECT)
+/-symbol	e/E	List symbol definition directives
+/-macro	m/M	List macro definitions
+/-empty-line	n/N	List empty source lines and comment lines (newline)
+/-conditional	p/P	List conditional assembly
+/-equate	q/Q	List equate and set directives (.EQU, .SET)
+/-relocations	r/R	List relocations characters ('r')
+/-equate-values	v/V	List equate and set values
+/-wrap-lines	w/W	Wrap source lines
+/-macro-expansion	x/X	List macro expansions
+/-cycle-count	y/Y	List cycle counts
+/-define-expansion	z/Z	List define expansions

Use the following options for predefined sets of flags:

<code>--list-format=0</code>	<code>-L0</code>	All options disabled Alias for <code>--list-format=DEMNPQRVWXYZ</code>
<code>--list-format=1</code>	<code>-L1</code>	All options enabled Alias for <code>--list-format=demnpqrvwxyz</code>

Default: `--list-format=dEMnPqrVwXyZ`

Description

With this option you specify which information you want to include in the list file.

On the command line you must use this option in combination with the option `--list-file (-I)`.

Related information

Assembler option **--list-file** (Generate list file)

Assembler option **--section-info=+list** (Display section information in list file)

Assembler option: **--make-target**

Menu entry

-

Command line syntax

--make-target=*name*

Description

With this option you can overrule the default target name in the make dependencies generated by the option **--dep-file**. The default target name is the basename of the input file, with extension `.o`.

Example

```
asmcs --dep-file --make-target=./mytarget.o test.asm
```

The assembler generates dependency lines with the default target name `./mytarget.o` instead of `test.o`.

Related information

Assembler option **--dep-file** (Generate dependencies in a file)

Assembler option: --no-notes

Menu entry

1. Select **Assembler » Miscellaneous**.
2. Add the option **--no-notes** to the **Additional options** field.

Command line syntax

--no-notes

Description

By default, the assembler generates a note section in the object file. The note section contains compiler version and invocation information, if supplied in the input file, and version and invocation information of the assembler. With this option you can suppress the generation of a note section in the output object file.

Related information

Section 6.4.2, *HLL Dump Output Format*

Assembler option: --no-warnings (-w)

Menu entry

1. Select **Assembler » Diagnostics**.

The Suppress warnings box shows the warnings that are currently suppressed.

2. To suppress a warning, click on the **Add** button in the **Suppress warnings** box.
3. Enter the numbers, separated by commas, of the warnings you want to suppress (for example 201, 202). Or you can use the **Add** button multiple times.
4. To suppress all warnings, enable the option **Suppress all warnings**.

Use the **Edit** and **Delete** button to change a warning number or to remove a number from the list.

Command line syntax

`--no-warnings[=number, ...]`

`-w[number, ...]`

Description

With this option you can suppresses all warning messages or specific warning messages.

On the command line this option works as follows:

- If you do not specify this option, all warnings are reported.
- If you specify this option but without numbers, all warnings are suppressed.
- If you specify this option with a number, only the specified warning is suppressed. You can specify the option `--no-warnings=number` multiple times.

Example

To suppress warnings 201 and 202, enter:

```
asmcs test.asm --no-warnings=201,202
```

Related information

[Assembler option --warnings-as-errors](#) (Treat warnings as errors)

Assembler option: `--option-file (-f)`

Menu entry

1. Select **Assembler » Miscellaneous**.
2. Add the option `--option-file` to the **Additional options** field.

Be aware that the options in the option file are added to the assembler options you have set in the other pages. Only in extraordinary cases you may want to use them in combination.

Command line syntax

```
--option-file=file,...
```

```
-f file,...
```

Description

This option is primarily intended for command line use. Instead of typing all options on the command line, you can create an option file which contains all options and flags you want to specify. With this option you specify the option file to the assembler.

Use an option file when the command line would exceed the limits of the operating system, or just to store options and save typing.

Option files can also be generated on the fly, for example by the make utility. You can specify the option `--option-file` multiple times.

Format of an option file

- Multiple arguments on one line in the option file are allowed.
- To include whitespace in an argument, surround the argument with single or double quotes.
- If you want to use single quotes as part of the argument, surround the argument by double quotes and vice versa:

```
"This has a single quote ' embedded"
```

```
'This has a double quote " embedded'
```

```
'This has a double quote " and a single quote ''' embedded"
```

- When a text line reaches its length limit, use a `\` to continue the line. Whitespace between quotes is preserved.

```
"This is a continuation \  
line"
```

```
-> "This is a continuation line"
```

TASKING VX-toolset for MCS User Guide

- It is possible to nest command line files up to 25 levels.

Example

Suppose the file `myoptions` contains the following lines:

```
--debug-info=+asm,-local  
test.asm
```

Specify the option file to the assembler:

```
asmcs --option-file=myoptions
```

This is equivalent to the following command line:

```
asmcs --debug-info=+asm,-local test.asm
```

Related information

-

Assembler option: --output (-o)

Menu entry

Eclipse names the output file always after the input file.

Command line syntax

```
--output=file
```

```
-o file
```

Description

With this option you can specify another filename for the output file of the assembler. Without this option, the basename of the assembly source file is used with extension `.o`.

Example

To create the file `relobj.o` instead of `asm.o`, enter:

```
asmcs --output=relobj.o asm.asm
```

Related information

-

Assembler option: --page-length

Menu entry

1. Select **Assembler » Miscellaneous**.
2. Add the option **--page-length** to the **Additional options** field.

Command line syntax

`--page-length=number`

Default: 72

Description

If you generate a list file with the assembler option **--list-file**, this option sets the number of lines in a page in the list file. The default is 72, the minimum is 10. As a special case, a page length of 0 turns off page breaks.

Related information

Assembler option **--list-file** (Generate list file)

Assembler control **\$PAGE**

Assembler option: `--page-width`

Menu entry

1. Select **Assembler » Miscellaneous**.
2. Add the option `--page-width` to the **Additional options** field.

Command line syntax

`--page-width=number`

Default: 132

Description

If you generate a list file with the assembler option `--list-file`, this option sets the number of columns per line on a page in the list file. The default is 132, the minimum is 40.

Related information

[Assembler option `--list-file`](#) (Generate list file)

[Assembler control `\$PAGE`](#)

Assembler option: **--preprocess (-E)**

Menu entry

-

Command line syntax

--preprocess

-E

Description

With this option the assembler will only preprocess the assembly source file. The assembler sends the preprocessed file to stdout.

Related information

-

Assembler option: `--preprocessor-type (-m)`

Menu entry

-

Command line syntax

`--preprocessor-type=type`

`-mtype`

You can set the following preprocessor types:

none	n	No preprocessor
tasking	t	TASKING preprocessor

Default: `--preprocessor-type=tasking`

Description

With this option you select the preprocessor that the assembler will use. By default, the assembler uses the TASKING preprocessor.

When the assembly source file does not contain any preprocessor symbols, you can specify to the assembler not to use a preprocessor.

Related information

-

Assembler option: **--section-info (-t)**

Menu entry

1. Select **Assembler » List File**.
2. Enable the option **Generate list file**.
3. Enable the option **List section summary**.

and/or

1. Select **Assembler » Diagnostics**.
2. Enable the option **Display section summary**.

Command line syntax

`--section-info[=flag,...]`

`-t[flags]`

You can set the following flags:

+/-console	c/C	Display section summary on console
+/-list	I/L	List section summary in list file

Default: `--section-info=CL`

Default (without flags): `--section-info=c1`

Description

With this option you tell the assembler to display section information. For each section its memory space, size, total cycle counts and name is listed on stdout and/or in the list file.

The cycle count consists of two parts: the total accumulated count for the section and the total accumulated count for all repeated instructions. In the case of nested loops it is possible that the total supersedes the section total.

Example

To write the section information to the list file and also display the section information on stdout, enter:

```
asmcs --list-file --section-info asm.asm
```

Related information

[Assembler option --list-file](#) (Generate list file)

Assembler option: `--symbol-scope (-i)`

Menu entry

1. Select **Assembler » Symbols**.
2. Enable or disable the option **Set default symbol scope to global**.

Command line syntax

`--symbol-scope=scope`

`-iscope`

You can set the following scope:

global	g	Default symbol scope is global
local	l	Default symbol scope is local

Default: `--symbol-scope=local`

Description

With this option you tell the assembler how to treat symbols that you have not specified explicitly as global or local. By default the assembler treats all symbols as local symbols unless you have defined them explicitly as global.

Related information

Assembler directive **.GLOBAL**

Assembler directive **.LOCAL**

Assembler control **\$IDENT**

Assembler option: --version (-V)

Menu entry

-

Command line syntax

`--version`

`-V`

Description

Display version information. The assembler ignores all other options or input files.

Related information

-

Assembler option: `--warnings-as-errors`

Menu entry

1. Select **Global Options**.
2. Enable the option **Treat warnings as errors**.

Command line syntax

`--warnings-as-errors` [=number, ...]

Description

If the assembler encounters an error, it stops assembling. When you use this option without arguments, you tell the assembler to treat all warnings as errors. This means that the exit status of the assembler will be non-zero after one or more assembler warnings. As a consequence, the assembler now also stops after encountering a warning.

You can limit this option to specific warnings by specifying a comma-separated list of warning numbers.

Related information

Assembler option `--no-warnings` (Suppress some or all warnings)

8.3. Linker Options

This section lists all linker options.

Options in Eclipse versus options on the command line

Most command line options have an equivalent option in Eclipse but some options are only available on the command line. Eclipse invokes the linker via the control program. Therefore, it uses the syntax of the control program to pass options and files to the linker. If there is no equivalent option in Eclipse, you can specify a command line option in Eclipse as follows:

1. From the **Project** menu, select **Properties for**

The Properties dialog appears.

2. In the left pane, expand **C/C++ Build** and select **Settings**.

In the right pane the Settings appear.

3. On the Tool Settings tab, select **Linker » Miscellaneous**.

4. In the **Additional options** field, enter one or more command line options.

*Because Eclipse uses the control program, Eclipse automatically precedes the option with **-Wl** to pass the option via the control program directly to the linker.*

Be aware that some command line options are not useful in Eclipse or just do not have any effect. For example, the option **--keep-output-files** keeps files after an error occurred. When you specify this option in Eclipse, it will have no effect because Eclipse always removes the output file after an error had occurred.

Short and long option names

Options can have both short and long names. Short option names always begin with a single minus (-) character, long option names always begin with two minus (--) characters. You can abbreviate long option names as long as it forms a unique name. You can mix short and long option names on the command line.

Options can have flags or suboptions. To switch a flag 'on', use a lowercase letter or a *+longflag*. To switch a flag off, use an uppercase letter or a *-longflag*. Separate *longflags* with commas. The following two invocations are equivalent:

```
lmcs -mfkl test.o
lmcs --map-file-format=+files,+link,+locate test.o
```

When you do not specify an option, a default value may become active.

Linker option: `--case-insensitive`

Menu entry

1. Select **Linker » Miscellaneous**.
2. Enable the option **Link case insensitive**.

Command line syntax

`--case-insensitive`

Default: case sensitive

Description

With this option you tell the linker not to distinguish between uppercase and lowercase characters in symbols. By default the linker considers uppercase and lowercase characters as different characters.

When you have written your own assembly code and specified to assemble it case insensitive, you must also link the `.o` file case insensitive.

Related information

Assembler option `--case-insensitive`

Linker option: **--c-array-element-type**

Menu entry

-

Command line syntax

--c-array-element-type=*string*

Default: `unsigned long`

Description

With this option you can overrule the C data type to be used for all C array elements in a C array output file. The type must be an integral type. Without this option the default data type is `unsigned long`.

Related information

Section 12.4, *C Array Format*

Linker option **--chip-output** (Generate an output file for each chip)

Linker option: `--chip-output (-c)`

Menu entry

1. Select **Linker » Output Format**.
2. Enable the option **Generate Intel Hex format file** and/or **Generate S-records file** and/or **Generate C array file**.
3. Enable the option **Create file for each memory chip**.
4. Optionally, specify the **Size of addresses**.

Eclipse always uses the project name as the basename for the output file.

Command line syntax

```
--chip-output=[basename]:format[:addr_size],...
```

```
-c[basename]:format[:addr_size],...
```

You can specify the following formats:

IHEX	Intel Hex
SREC	Motorola S-records
BIN	Binary
CARR	C array

For Intel Hex and Motorola S-records the *addr_size* specifies the size of the addresses in bytes (record length). For Intel Hex you can use the values **1**, **2** or **4** bytes (default). For Motorola S you can specify: **2** (S1 records), **3** (S2 records) or **4** bytes (S3 records, default). For C array files, the address size specifies the number of bits stored in each array element.

Description

With this option the linker generates an output file for each memory chip in the specified format: Intel Hex, Motorola S-records, binary or C array. You can use the Intel Hex or Motorola S-record output for loading into a PROM-programmer, or you can use the binary or C array output for importing the application into a host application. The C array format contains the generated machine code in the form of C code. For more information see [Section 12.4, C Array Format](#).

The linker generates a file for each ROM or RAM memory defined in the LSL file, where one or more initialized sections are located. For example:

```
memory memname
{ type=rom; }
```

The name of the file is the name of the Eclipse project or, on the command line, the name of the memory device that was emitted with extension `.hex` (Intel Hex), `.srec` (Motorola S-records) or `.bin` (binary without metadata). For the C array format the output is a `.c` file for the array definition and a `.h` file for

the accompanying header file. Optionally, you can specify a *basename* which prepends the generated file name.

The linker always outputs a debugging file in ELF/DWARF format and optionally an output as specified with this option.

Use linker option **--output** for the debugging file and/or for hex files at space level.

Example

To generate Intel Hex output files for each defined memory, enter the following on the command line:

```
lmcs --chip-output=myfile:IHEX test1.o
```

In this case, this generates the file `myfile_memname.hex`.

To generate C array output files for each defined memory, enter the following on the command line:

```
lmcs --chip-output=myfile:CARR:32 test1.o
```

In this case, this generates the files `myfile_memname.c` and `myfile_memname.h`.

Related information

[Chapter 12, Object File Formats](#)

[Linker option --output \(Output file\)](#)

[Linker option --hex-format \(Specify Hex file or C array format settings\)](#)

Linker option: **--core (-C)**

Menu entry

1. Expand **C/C++ Build** and select **Processor**.
2. From the **Processor Selection** list, select a processor or select **User defined ...**.
3. From the **Multi-core configuration** list, select an MCS core.

Command line syntax

`--core=MCS-core`

`-CMCS-core`

You can specify the following MCS cores (depending on the chosen processor):

mcs00	MCS core 0
mcs01	MCS core 1
mcs02	MCS core 2
mcs03	MCS core 3
mcs04	MCS core 4
mcs05	MCS core 5
mcs06	MCS core 6
mcs07	MCS core 7
mcs08	MCS core 8
mcs09	MCS core 9

Default: **mcs00**

Description

With this option you specify the core for the target processor for which you create your application.

In a multi-task setting, use this option to tell the linker to use a specific core for a specific task. Only one task can be assigned to a certain core. Assigning multiple tasks to a single core requires some form of kernel functionality.

Example

To link objects for the MCS core `mcs01`, enter:

```
lmcs -o test.out -dtc39xb.lsl --core=mcs01
      --endianess=little -D__CPU__=tc39xb -D__PROC_TC39XB__
      --link-only -D__LINKONLY__ --map-file test.o
      "-Lpath\lib\mcs31\le" -lc -lfp -lrt
```

Related information

Control program option **--lsl-core** (Specify LSL core)

Linker option: `--define (-D)`

Menu entry

1. Select **Linker » Script File**.

The Defined symbols box shows the symbols that are currently defined.

2. To define a new symbol, click on the **Add** button in the **Defined symbols** box.
3. Type the symbol definition (for example, `demo=1`)

Use the **Edit** and **Delete** button to change a macro definition or to remove a macro from the list.

Command line syntax

```
--define=macro_name[=macro_definition]
```

```
-Dmacro_name[=macro_definition]
```

Description

With this option you can define a macro and specify it to the linker LSL file preprocessor. If you only specify a macro name (no macro definition), the macro expands as '1'.

You can specify as many macros as you like; just use the option `--define (-D)` multiple times. If the command line exceeds the limit of the operating system, you can define the macros in an option file which you then must specify to the linker with the option `--option-file (-f) file`.

The definition can be tested by the preprocessor with `#if`, `#ifdef` and `#ifndef`, for conditional locating.

Make sure you do not use a reserved keyword as a macro name, as this can lead to unexpected results.

Example

To define the RESET vector, which is used in the linker script file `tc39xb.lsl`, enter:

```
lmcs test.o -otest.elf --lsl-file=tc39xb.lsl --define=RESET=0xa0000020
```

Related information

Linker option `--option-file` (Specify an option file)

Linker option: --diag

Menu entry

1. From the **Window** menu, select **Show View » Other » TASKING » Problems**.

The Problems view is added to the current perspective.

2. In the Problems view right-click on a message.

A popup menu appears.

3. Select **Detailed Diagnostics Info**.

A dialog box appears with additional information.

Command line syntax

```
--diag=[format:]{all | nr,...}
```

You can set the following output formats:

html	HTML output.
rtf	Rich Text Format.
text	ASCII text.

Default format: text

Description

With this option you can ask for an extended description of error messages in the format you choose. The output is directed to stdout (normally your screen) and in the format you specify. You can specify the following formats: **html**, **rtf** or **text** (default). To create a file with the descriptions, you must redirect the output.

With the suboption **all**, the descriptions of all error messages are given. If you want the description of one or more selected error messages, you can specify the error message numbers, separated by commas.

With this option the linker does not link/locate any files.

Example

To display an explanation of message number 106, enter:

```
lmcs --diag=106
```

This results in the following message and explanation:

```
E106: unresolved external: <message>
```

The linker could not resolve all external symbols.

This is an error when the incremental linking option is disabled. The `<message>` indicates the symbol that is unresolved.

To write an explanation of all errors and warnings in HTML format to file `lkerrors.html`, use redirection and enter:

```
lmcs --diag=html:all > lkerrors.html
```

Related information

[Section 5.10, *Linker Error Messages*](#)

Linker option: **--endianness**

Menu entry

1. Select **Global Options**.
2. Specify the **Endianness:Little-endian mode** or **Big-endian mode**.

Command line syntax

--endianness=*endianness*

-B

--big-endian

You can specify the following *endianness*:

big	b	Big endian
little	l	Little endian (default)

Description

By default, the linker links objects in little-endian mode. With **--endianness=big** you tell the linker to link the input files in big-endian mode. The endianness used must be valid for the architecture you are linking for. Depending on the endianness used, the linker links different libraries. **-B** is an alias for option **--endianness=big**.

Related information

Linker option: `--error-file`

Menu entry

-

Command line syntax

```
--error-file[=file]
```

Description

With this option the linker redirects diagnostic messages to a file. If you do not specify a filename, the error file is `lmcs.elk`.

Example

To write diagnostic messages to `errors.elk` instead of `stderr`, enter:

```
lmcs --error-file=errors.elk test.o
```

Related information

Section 5.10, *Linker Error Messages*

Linker option: **--error-limit**

Menu entry

1. Select **Linker » Diagnostics**.
2. Enter a value in the **Maximum number of emitted errors** field.

Command line syntax

`--error-limit=number`

Default: 42

Description

With this option you tell the linker to only emit the specified maximum number of errors. When 0 (null) is specified, the linker emits all errors. Without this option the maximum number of errors is 42.

Related information

Section 5.10, *Linker Error Messages*

Linker option: `--extern (-e)`

Menu entry

-

Command line syntax

```
--extern=symbol,...
```

```
-esymbol,...
```

Description

With this option you force the linker to consider the given symbol as an undefined reference. The linker tries to resolve this symbol, either the symbol is defined in an object file or the linker extracts the corresponding symbol definition from a library.

This option is, for example, useful if the startup code is part of a library. Because your own application does not refer to the startup code, you can force the startup code to be extracted by specifying the symbol `_START` as an unresolved external.

Example

Consider the following invocation:

```
lmcs mylib.a
```

Nothing is linked and no output file will be produced, because there are no unresolved symbols when the linker searches through `mylib.a`.

```
lmcs --extern=_START mylib.a
```

In this case the linker searches for the symbol `_START` in the library and (if found) extracts the object that contains `_START`, the startup code. If this module contains new unresolved symbols, the linker looks again in `mylib.a`. This process repeats until no new unresolved symbols are found.

Related information

-

Linker option: **--first-library-first**

Menu entry

-

Command line syntax

--first-library-first

Description

When the linker processes a library it searches for symbols that are referenced by the objects and libraries processed so far. If the library contains a definition for an unresolved reference the linker extracts the object that contains the definition from the library.

By default the linker processes object files and libraries in the order in which they appear on the command line. If you specify the option **--first-library-first** the linker always tries to take the symbol definition from the library that appears first on the command line before scanning subsequent libraries.

This is for example useful when you are working with a newer version of a library that partially overlaps the older version. Because they do not contain exactly the same functions, you have to link them both. However, when a function is present in both libraries, you may want the linker to extract the most recent function.

Example

Consider the following example:

```
lmcs --first-library-first a.a test.o b.a
```

If the file `test.o` calls a function which is both present in `a.a` and `b.a`, normally the function in `b.a` would be extracted. With this option the linker first tries to extract the symbol from the first library `a.a`.

Note that routines in `b.a` that call other routines that are present in both `a.a` and `b.a` are now also resolved from `a.a`.

Related information

Linker option **--no-rescan** (Rescan libraries to solve unresolved externals)

Linker option: --global-type-checking

Menu entry

-

Command line syntax

`--global-type-checking`

Description

Use this option when you want the linker to check the types of variable and function references against their definitions, using DWARF 3 debug information.

Related information

-

Linker option: --help (-?)

Menu entry

-

Command line syntax

`--help[=item]`

`-?`

You can specify the following arguments:

options	Show extended option descriptions
----------------	-----------------------------------

Description

Displays an overview of all command line options. When you specify the argument **options** you can list detailed option descriptions.

Example

The following invocations all display a list of the available command line options:

```
lmcs -?  
lmcs --help  
lmcs
```

To see a detailed description of the available options, enter:

```
lmcs --help=options
```

Related information

-

Linker option: `--hex-format`

Menu entry

1. Select **Linker » Output Format**.
2. Enable the option **Generate Intel Hex format file** and enable or disable the option **Emit start address record**.
3. Enable the option **Generate C array file** and enable or disable the option **Emit list of exported symbols**.

Command line syntax

`--hex-format=flag,...`

You can set the following flag:

+/-start-address	s/S	Emit start address record
+/-c-array-symbols	y/Y	Emit list of exported symbols

Default: `--hex-format=s`

Description

With this option you can specify to emit or omit the start address record from the hex file or you can emit a list of exported symbols for C array files.

Related information

[Chapter 12, Object File Formats](#)

Linker option `--output` (Output file)

Linker option `--chip-output` (Generate an output file for each chip)

Linker option: **--hex-record-size**

Menu entry

1. Select **Linker » Miscellaneous**.
2. Add the option **--hex-record-size** to the **Additional options** field.

Command line syntax

--hex-record-size=*size*

Default: 32

Description

With this option you can set the size (width) of the Intel Hex data records.

Related information

Linker option **--output** (Output file)

Linker option: `--import-object`

Menu entry

1. Select **Linker » Data Objects**.

The Data objects box shows the list of object files that are imported.

2. To add a data object, click on the **Add** button in the **Data objects** box.
3. Type or select a binary file (including its path).

Use the **Edit** and **Delete** button to change a filename or to remove a data object from the list.

Command line syntax

```
--import-object=file,...
```

Description

With this option the linker imports a binary *file* containing raw data and places it in a section. The section name is derived from the filename, in which dots are replaced by an underscore. So, when importing a file called `my.jpg`, a section with the name `my_jpg` is created. In your application you can refer to the created section by using linker labels.

Related information

[Section 5.5, *Importing Binary Files*](#)

Linker option: **--include-directory (-I)**

Menu entry

-

Command line syntax

--include-directory=*path*,...

-I*path*,...

Description

With this option you can specify the path where your LSL include files are located. A relative path will be relative to the current directory.

The order in which the linker searches for LSL include files is:

1. The pathname in the LSL file and the directory where the LSL file is located (only for #include files that are enclosed in "")
2. The path that is specified with this option.
3. The default directory $\$(PRODDIR)\include.lsl$.

Example

Suppose that your linker script file `mylsl.lsl` contains the following line:

```
#include "myinc.inc"
```

You can call the linker as follows:

```
lmcs --include-directory=c:\proj\include --lsl-file=mylsl.lsl test.o
```

First the linker looks for the file `myinc.inc` in the directory where `mylsl.lsl` is located. If it does not find the file, it looks in the directory `c:\proj\include` (this option). Finally it looks in the directory $\$(PRODDIR)\include.lsl$.

Related information

Linker option **--lsl-file** (Specify linker script file)

Linker option: --incremental (-r)

Menu entry

-

Command line syntax

`--incremental`

`-r`

Description

Normally the linker links and locates the specified object files. With this option you tell the linker only to link the specified files. The linker creates a linker output file `.out`. You then can link this file again with other object files until you have reached the final linker output file that is ready for locating.

In the last pass, you call the linker without this option with the final linker output file `.out`. The linker will now locate the file.

Example

In this example, the files `test1.o`, `test2.o` and `test3.o` are incrementally linked:

```
1. lmcs --incremental test1.o test2.o --output=test.out
```

test1.o and test2.o are linked

```
2. lmcs --incremental test3.o test.out
```

test3.o and test.out are linked, task1.out is created

```
3. lmcs task1.out
```

task1.out is located

Related information

[Section 5.4, Incremental Linking](#)

Linker option: **--keep-output-files (-k)**

Menu entry

Eclipse *always* removes the output files when errors occurred.

Command line syntax

--keep-output-files

-k

Description

If an error occurs during linking, the resulting output file may be incomplete or incorrect. With this option you keep the generated output files when an error occurs.

By default the linker removes the generated output file when an error occurs. This is useful when you use the make utility. If the erroneous files are not removed, the make utility may process corrupt files on a subsequent invocation.

Use this option when you still want to use the generated file. For example when you know that a particular error does not result in a corrupt object file, or when you want to inspect the output file, or send it to Altium support.

Related information

Linker option **--warnings-as-errors** (Treat warnings as errors)

Linker option: `--library (-l)`

Menu entry

1. Select **Linker » Libraries**.

The Libraries box shows the list of libraries that are linked with the project.

2. To add a library, click on the **Add** button in the **Libraries** box.
3. Type or select a library (including its path).
4. Optionally, disable the option **Link default libraries**.

Use the **Edit** and **Delete** button to change a library name or to remove a library from the list.

Command line syntax

`--library=name`

`-lname`

Description

With this option you tell the linker to use system library `libname.a`, where `name` is a string. The linker first searches for system libraries in any directories specified with `--library-directory`, then in the directories specified with the environment variable `LIBMCS`, unless you used the option `--ignore-default-library-path`.

Example

To search in the system library `libc.a`:

```
lmcs test.o mylib.a --library=c
```

The linker links the file `test.o` and first looks in library `mylib.a` (in the current directory only), then in the system library `libc.a` to resolve unresolved symbols.

Related information

Linker option `--library-directory` (Additional search path for system libraries)

-

Linker option: **--library-directory (-L) / --ignore-default-library-path**

Menu entry

1. Select **Linker » Libraries**.

The Library search path box shows the directories that are added to the search path for library files.

2. To define a new directory for the search path, click on the **Add** button in the **Library search path** box.
3. Type or select a path.

Use the **Edit** and **Delete** button to change a path or to remove a path from the list.

Command line syntax

--library-directory=*path*,...

-L*path*,...

--ignore-default-library-path

-L

Description

With this option you can specify the path(s) where your system libraries, specified with the option **--library (-l)**, are located. If you want to specify multiple paths, use the option **--library-directory** for each separate path.

The default path is `$(PRODDIR)\lib`.

If you specify only **-L** (without a pathname) or the long option **--ignore-default-library-path**, the linker will not search the default path and also not in the paths specified in the environment variable `LIBMCS`. So, the linker ignores steps 2 and 3 as listed below.

The priority order in which the linker searches for system libraries specified with the option **--library (-l)** is:

1. The path that is specified with the option **--library-directory**.
2. The path that is specified in the environment variable `LIBMCS`.
3. The default directory `$(PRODDIR)\lib`.

Example

Suppose you call the linker as follows:

```
lmcs test.o --library-directory=c:\mylibs --library=c
```

First the linker looks in the directory `c:\mylibs` for library `libc.a` (this option). If it does not find the requested libraries, it looks in the directory that is set with the environment variable `LIBMCS`. Then the linker looks in the default directory `$(PRODDIR)\lib` for libraries.

Related information

Linker option **--library** (Link system library)

-

Linker option: **--link-only**

Menu entry

-

Command line syntax

`--link-only`

Description

With this option you suppress the locating phase. The linker stops after linking and informs you about unresolved references.

Related information

Control program option `--create=relocatable (-cl)` (Stop after linking)

Linker option: **--lsl-check**

Menu entry

-

Command line syntax

--lsl-check

Description

With this option the linker just checks the syntax of the LSL file(s) and exits. No linking or locating is performed. Use the option **--lsl-file** to specify the name of the Linker Script File you want to test.

Related information

Linker option **--lsl-file** (Linker script file)

Linker option **--lsl-dump** (Dump LSL info)

Section 5.7, *Controlling the Linker with a Script*

Linker option: **--lsl-dump**

Menu entry

-

Command line syntax

--lsl-dump[=*file*]

Description

With this option you tell the linker to dump the LSL part of the map file in a separate file, independent of the option **--map-file** (generate map file). If you do not specify a filename, the file `lmcs.ldf` is used.

Related information

Linker option **--map-file-format** (Map file formatting)

Linker option: `--lsl-file (-d)`

Menu entry

An LSL file can be generated when you create your TriCore project in Eclipse:

1. From the **File** menu, select **File » New » TASKING TriCore C/C++ Project**.

The New C/C++ Project wizard appears.

2. Fill in the project settings in each dialog and click **Next >** until the **TriCore Project Settings** appear.
3. Enable the option **Add linker script file to the project** and click **Finish**.

Eclipse creates your project and the file `project.lsl` in the project directory.

The LSL file can be specified in the Properties dialog:

1. Select **Linker » Script File**.
2. Specify a LSL file in the **Linker script file (.lsl)** field.

Command line syntax

```
--lsl-file=file
```

```
-dfile
```

Description

A linker script file contains vital information about the core for the locating phase of the linker. A linker script file is coded in LSL and contains the following types of information:

- the architecture definition describes the core's hardware architecture.
- the memory definition describes the physical memory available in the system.
- the section layout definition describes how to locate sections in memory.

With this option you specify a linker script file to the linker. If you do not specify this option, the linker uses a default script file. You can specify the existing file `target.lsl` or the name of a manually written linker script file. You can use this option multiple times. The linker processes the LSL files in the order in which they appear on the command line.

Related information

Linker option `--lsl-check` (Check LSL file(s) and exit)

Section 5.7, *Controlling the Linker with a Script*

Linker option: --map-file (-M)

Menu entry

1. Select **Linker » Map File**.
2. Enable the option **Generate XML map file format (.mapxml) for map file viewer**.
3. (Optional) Enable the option **Generate map file**.
4. Enable or disable the types of information to be included.

Command line syntax

```
--map-file[=file][:XML]
```

```
-M[file][:XML]
```

Default (Eclipse): XML map file is generated

Default (linker): no map file is generated

Description

With this option you tell the linker to generate a linker map file. If you do not specify a filename and you specified the option **--output**, the linker uses the same basename as the output file with the extension `.map`. If you did not specify the option **--output**, the linker uses the file `task1.map`. Eclipse names the `.map` file after the project.

A linker map file is a text file that shows how the linker has mapped the sections and symbols from the various object files (`.o`) to the linked object file. A locate part shows the absolute position of each section. External symbols are listed per space with their absolute address, both sorted on symbol and sorted on address.

Related information

Linker option **--map-file-format** (Format map file)

Section 11.2, *Linker Map File Format*

Linker option: --map-file-format (-m)

Menu entry

1. Select **Linker » Map File**.
2. Enable the option **Generate XML map file format (.mapxml) for map file viewer**.
3. (Optional) Enable the option **Generate map file**.
4. Enable or disable the types of information to be included.

Command line syntax

`--map-file-format=flag,...`

`-mflags`

You can set the following flags:

+/-callgraph	c/C	Include call graph information
+/-removed	d/D	Include information on removed sections
+/-files	f/F	Include processed files information
+/-invocation	i/I	Include information on invocation and tools
+/-link	k/K	Include link result information
+/-locate	l/L	Include locate result information
+/-memory	m/M	Include memory usage information
+/-nonalloc	n/N	Include information of non-alloc sections
+/-overlay	o/O	Include overlay information
+/-statics	q/Q	Include module local symbols information
+/-crossref	r/R	Include cross references information
+/-lsl	s/S	Include processor and memory information
+/-rules	u/U	Include locate rules

Use the following options for predefined sets of flags:

<code>--map-file-format=0</code>	-m0	Link information Alias for -mCDfikLMNoQrSU
<code>--map-file-format=1</code>	-m1	Locate information Alias for -mCDfiKIMNoQRSU
<code>--map-file-format=2</code>	-m2	Most information Alias for -mcdfiklmNoQrSu

Default: `--map-file-format=2`

Description

With this option you specify which information you want to include in the map file.

On the command line you must use this option in combination with the option **--map-file (-M)**.

Related information

Linker option **--map-file** (Generate map file)

Section 11.2, *Linker Map File Format*

Linker option: `--misra-c-report`

Menu entry

-

Command line syntax

```
--misra-c-report[=file]
```

Description

With this option you tell the linker to create a MISRA C Quality Assurance report. This report lists the various modules in the project with the respective MISRA C settings at the time of compilation. If you do not specify a filename, the file *basename.mcr* is used.

Related information

C compiler option `--misrac` (MISRA C checking)

Linker option: `--new-task`

Menu entry

-

Command line syntax

`--new-task`

Description

With this option the linker creates an additional task. Any options that follow only apply to the new task.

The linker processes options on the command line from left to right. To know whether a certain option belongs to a different task it uses this option. This implies that all options for a given task must be fully specified before moving on to the next.

Related information

-

Linker option: **--non-romable**

Menu entry

-

Command line syntax

--non-romable

Description

With this option you tell the linker that the application must not be located in ROM. The linker will locate all ROM sections, including a copy table if present, in RAM. When the application is started, the data sections are re-initialized and the BSS sections are cleared as usual.

This option is, for example, useful when you want to test the application in RAM before you put the final application in ROM. This saves you the time of flashing the application in ROM over and over again.

If you want to locate your application in RAM only, without using ROM/flash resources of the chip, for example when you run the debugger in RAM only, also specify the options **--no-rom-copy** and **--user-provided-initialization-code** or use the control program option **--meminit=none**.

Related information

Control program option **--meminit** (Initialize memory)

Linker option **--no-rom-copy** (Do not generate ROM copy)

Linker option **--user-provided-initialization-code** (Own initialization code, no standard copy table)

Linker option: **--no-rescan**

Menu entry

1. Select **Linker » Libraries**.
2. Disable the option **Rescan libraries to solve unresolved externals**.

Command line syntax

--no-rescan

Description

When the linker processes a library it searches for symbol definitions that are referenced by the objects and libraries processed so far. If the library contains a definition for an unresolved reference the linker extracts the object that contains the definition from the library. The linker processes object files and libraries in the order in which they appear on the command line.

When all objects and libraries are processed the linker checks if there are unresolved symbols left. If so, the default behavior of the linker is to rescan all libraries in the order given at the command line. The linker stops rescanning the libraries when all symbols are resolved, or when the linker could not resolve any symbol(s) during the rescan of all libraries. Notice that resolving one symbol may introduce new unresolved symbols.

With this option, you tell the linker to scan the object files and libraries only once. When the linker has not resolved all symbols after the first scan, it reports which symbols are still unresolved. This option is useful if you are building your own libraries. The libraries are most efficiently organized if the linker needs only one pass to resolve all symbols.

Related information

[Linker option **--first-library-first**](#) (Scan libraries in given order)

Linker option: **--no-rom-copy (-N)**

Menu entry

-

Command line syntax

`--no-rom-copy`

`-N`

Description

With this option the linker will not generate a ROM copy for data sections. A copy table is generated and contains entries to clear BSS sections. However, no entries to copy data sections from ROM to RAM are placed in the copy table.

The data sections are initialized when the application is downloaded. The data sections are not re-initialized when the application is restarted.

Related information

Linker option `--non-romable` (Application is not romable)

Linker option `--user-provided-initialization-code` (Own initialization code, no standard copy table)

Linker option: **--no-warnings (-w)**

Menu entry

1. Select **Linker » Diagnostics**.

The Suppress warnings box shows the warnings that are currently suppressed.

2. To suppress a warning, click on the **Add** button in the **Suppress warnings** box.
3. Enter the numbers, separated by commas, of the warnings you want to suppress (for example 135,136). Or you can use the **Add** button multiple times.
4. To suppress all warnings, enable the option **Suppress all warnings**.

Use the **Edit** and **Delete** button to change a warning number or to remove a number from the list.

Command line syntax

--no-warnings[=*number*, ...]

-w[*number*, ...]

Description

With this option you can suppresses all warning messages or specific warning messages.

On the command line this option works as follows:

- If you do not specify this option, all warnings are reported.
- If you specify this option but without numbers, all warnings are suppressed.
- If you specify this option with a number, only the specified warning is suppressed. You can specify the option **--no-warnings=number** multiple times.

Example

To suppress warnings 135 and 136, enter:

```
lmcs --no-warnings=135,136 test.o
```

Related information

[Linker option **--warnings-as-errors**](#) (Treat warnings as errors)

Linker option: --optimize (-O)

Menu entry

1. Select **Linker » Optimization**.
2. Select one or more of the following options:
 - Delete unreferenced sections
 - Use a 'first-fit decreasing' algorithm
 - Compress copy table
 - Delete duplicate code
 - Delete duplicate data

Command line syntax

`--optimize=flag,...`

`-Oflags`

You can set the following flags:

+/-delete-unreferenced-sections	c/C	Delete unreferenced sections from the output file
+/-first-fit-decreasing	I/L	Use a 'first-fit decreasing' algorithm to locate unrestricted sections in memory
+/-copytable-compression	t/T	Emit smart restrictions to reduce copy table size
+/-delete-duplicate-code	x/X	Delete duplicate code sections from the output file
+/-delete-duplicate-data	y/Y	Delete duplicate constant data from the output file

Use the following options for predefined sets of flags:

--optimize=0	-O0	No optimization Alias for -OCLTXy
--optimize=1	-O1	Default optimization Alias for -OcLtxy
--optimize=2	-O2	All optimizations Alias for -Ocltxy

Default: `--optimize=1`

Description

With this option you can control the level of optimization.

Note that when you use the flag **+copytable-compression**, sections affected by the copy table are located as if they were in a clustered LSL group, if they do not have a locate restriction yet.

Related information

For details about each optimization see [Section 5.6, *Linker Optimizations*](#).

Define the mutual order of sections in an LSL group in [Section 13.8.2, *Creating and Locating Groups of Sections*](#).

Linker option: **--option-file (-f)**

Menu entry

1. Select **Linker » Miscellaneous**.
2. Add the option **--option-file** to the **Additional options** field.

Be aware that the options in the option file are added to the linker options you have set in the other pages. Only in extraordinary cases you may want to use them in combination.

Command line syntax

```
--option-file=file,...
```

```
-f file,...
```

Description

This option is primarily intended for command line use. Instead of typing all options on the command line, you can create an option file which contains all options and flags you want to specify. With this option you specify the option file to the linker.

Use an option file when the command line would exceed the limits of the operating system, or just to store options and save typing.

Option files can also be generated on the fly, for example by the make utility. You can specify the option **--option-file** multiple times.

Format of an option file

- Multiple arguments on one line in the option file are allowed.
- To include whitespace in an argument, surround the argument with single or double quotes.
- If you want to use single quotes as part of the argument, surround the argument by double quotes and vice versa:

```
"This has a single quote ' embedded"
```

```
'This has a double quote " embedded'
```

```
'This has a double quote " and a single quote ''' embedded"
```

- When a text line reaches its length limit, use a `\` to continue the line. Whitespace between quotes is preserved.

```
"This is a continuation \  
line"
```

```
-> "This is a continuation line"
```

TASKING VX-toolset for MCS User Guide

- It is possible to nest command line files up to 25 levels.

Example

Suppose the file `myoptions` contains the following lines:

```
--map-file=my.map           (generate a map file)
test.o                     (input file)
--library-directory=c:\mylibs (additional search path for system libraries)
```

Specify the option file to the linker:

```
lmcs --option-file=myoptions
```

This is equivalent to the following command line:

```
lmcs --map-file=my.map test.o --library-directory=c:\mylibs
```

Related information

-

Linker option: **--output (-o)**

Menu entry

1. Select **Linker » Output Format**.
2. Enable one or more output formats.

For some output formats you can specify a number of suboptions.

Eclipse always uses the project name as the basename for the output file.

Command line syntax

```
--output=[filename][:format[:addr_size][,space_name]]...
```

```
-o[filename][:format[:addr_size][,space_name]]...
```

You can specify the following formats:

ELF	ELF/DWARF
IHEX	Intel Hex
SREC	Motorola S-records

Description

By default, the linker generates an output file in ELF/DWARF format, with the name `task1.elf`.

With this option you can specify an alternative *filename*, and an alternative output *format*. The default output format is the format of the first input file.

You can use the **--output** option multiple times. This is useful to generate multiple output formats. With the first occurrence of the **--output** option you specify the basename (the filename without extension), which is used for subsequent **--output** options with no filename specified. If you do not specify a filename, or you do not specify the **--output** option at all, the linker uses the default basename `taskn`.

IHEX and SREC formats

If you specify the Intel Hex format or the Motorola S-records format, you can use the argument *addr_size* to specify the size of addresses in bytes (record length). For Intel Hex you can use the values: 1, 2, and 4 (default). For Motorola S-records you can specify: 2 (S1 records), 3 (S2 records, default) or 4 bytes (S3 records). Note that if you make the *addr_size* too small, the linker might give a fatal object writer error indicating an address overflow.

With the argument *space_name* you can specify the name of the address space. The name of the output file will be *filename* with the extension `.hex` or `.sre` and contains the code and data allocated in the specified space. If they exist, any other address spaces are also emitted whereas their output files are named *filename_spacesname* with the extension `.hex` or `.sre`.

If you do not specify *space_name*, or you specify a non-existing space, the default address space is filled in.

TASKING VX-toolset for MCS User Guide

Use option **--chip-output (-c)** to create Intel Hex or Motorola S-record output files for each chip defined in the LSL file (suitable for loading into a PROM-programmer).

Example

To create the output file `myfile.hex` of the address space named `linear`, enter:

```
lmcs test.o --output=myfile.hex:IHEX:2,linear
```

If they exist, any other address spaces are emitted as well and are named `myfile_spacename.hex`.

Related information

[Linker option --chip-output](#) (Generate an output file for each chip)

[Linker option --hex-format](#) (Specify Hex file or C array format settings)

Linker option: **--strip-debug (-S)**

Menu entry

1. Select **Linker » Miscellaneous**.
2. Enable the option **Strip symbolic debug information**.

Command line syntax

`--strip-debug`

`-S`

Description

With this option you specify not to include symbolic debug information in the resulting output file.

Related information

-

Linker option: **--user-provided-initialization-code (-i)**

Menu entry

1. Select **Linker » Miscellaneous**.
2. Enable the option **Do not use standard copy table for initialization**.

Command line syntax

`--user-provided-initialization-code`

`-i`

Description

It is possible to use your own initialization code, for example, to save ROM space. With this option you tell the linker *not* to generate a copy table for initialize/clear sections. Use linker labels in your source code to access the positions of the sections when located.

If the linker detects references to the TASKING initialization code, an error is emitted: it is either the TASKING initialization routine or your own, not both.

Note that the options **--no-rom-copy** and **--non-romable**, may vary independently. The 'copytable-compression' optimization (**--optimize=t**) is automatically disabled when you enable this option.

Related information

[Linker option **--no-rom-copy**](#) (Do not generate ROM copy)

[Linker option **--non-romable**](#) (Application is not romable)

[Linker option **--optimize**](#) (Specify optimization)

Linker option: `--verbose (-v)`

Menu entry

1. Select **Linker » Miscellaneous**.
2. Enable the option **Show link phases during processing**.

The verbose output is displayed in the Problems view and the Console view.

Command line syntax

`--verbose`

`-v`

Description

With this option you put the linker in *verbose* mode. The linker prints the link phases while it processes the files. The linker prints one entry for each action it executes for a task. When you use this option twice (`-vv`) you put the linker in *extra verbose* mode. In this mode the linker also prints the filenames and it shows which objects are extracted from libraries and it shows verbose information that would normally be hidden when you use the normal verbose mode or when you run without verbose. With this option you can monitor the current status of the linker.

Related information

-

Linker option: --version (-V)

Menu entry

-

Command line syntax

`--version`

`-V`

Description

Display version information. The linker ignores all other options or input files.

Related information

-

Linker option: `--warnings-as-errors`

Menu entry

1. Select **Global Options**.
2. Enable the option **Treat warnings as errors**.

Command line syntax

`--warnings-as-errors`[=*number*, ...]

Description

When the linker detects an error or warning, it tries to continue the link process and reports other errors and warnings. When you use this option without arguments, you tell the linker to treat all warnings as errors. This means that the exit status of the linker will be non-zero after the detection of one or more linker warnings. As a consequence, the linker will not produce any output files.

You can also limit this option to specific warnings by specifying a comma-separated list of warning numbers.

Related information

Linker option `--no-warnings` (Suppress some or all warnings)

Linker option: **--whole-archive**

Menu entry

1. Select **Linker » Miscellaneous**.
2. Add the option **--whole-archive** to the **Additional options** field.

Command line syntax

--whole-archive=*file*

Description

This option tells the linker to directly load all object modules in a library, as if they were placed on the command line. This is different from libraries specified as input files or with the **-l** option, which are only used to resolve references in object files that were loaded earlier.

Example

Suppose the library `myarchive.a` contains the objects `my1.o`, `my2.o` and `my3.o`. Specifying

```
lmcs --whole-archive=myarchive.a
```

is the same as specifying

```
lmcs my1.o my2.o my3.o
```

Related information

[Linker option **--library**](#) (Link system library)

8.4. Control Program Options

The control program **ccmcs** facilitates the invocation of the various components of the MCS toolset from a single command line.

Options in Eclipse versus options on the command line

Eclipse invokes the compiler, assembler and linker via the control program. Therefore, it uses the syntax of the control program to pass options and files to the tools. The control program processes command line options either by itself, or, when the option is unknown to the control program, it looks whether it can pass the option to one of the other tools. However, for directly passing an option to the C compiler, assembler or linker, it is recommended to use the control program options **--pass-c**, **--pass-assembler**, **--pass-linker**.

See the previous sections for details on the options of the tools.

Short and long option names

Options can have both short and long names. Short option names always begin with a single minus (-) character, long option names always begin with two minus (--) characters. You can abbreviate long option names as long as it forms a unique name. You can mix short and long option names on the command line.

Options can have flags or suboptions. To switch a flag 'on', use a lowercase letter or a *+longflag*. To switch a flag off, use an uppercase letter or a *-longflag*. Separate *longflags* with commas. The following two invocations are equivalent:

```
ccmcs -Wc-Oac test.c
ccmcs --pass-c=--optimize=+coalesce,+cse test.c
```

When you do not specify an option, a default value may become active.

Control program option: `--address-size`

Menu entry

1. Select **Linker » Output Format**.
2. Enable the option **Generate Intel Hex format file** and/or **Generate S-records file**.
3. Specify the **Size of addresses**.

Eclipse always uses the project name as the basename for the output file.

Command line syntax

```
--address-size=addr_size
```

Description

If you specify IHEX or SREC with the control option `--format`, you can additionally specify the record length to be emitted in the output files.

With this option you can specify the size of the addresses in bytes (record length). For Intel Hex you can use the values **1**, **2** or **4** bytes (default). For Motorola-S you can specify: **2** (S1 records), **3** (S2 records) or **4** bytes (S3 records, default).

If you do not specify `addr_size`, the default address size is generated.

Example

To create the SREC file `test.sre` with S1 records, type:

```
ccmcs --format=SREC --address-size=2 test.c
```

Related information

Control program option `--format` (Set linker output format)

Control program option `--output` (Output file)

Control program option: `--case-insensitive`

Menu entry

1. Select **Assembler » Symbols**.
2. Enable the option **Case insensitive identifiers**.

Command line syntax

`--case-insensitive`

Default: case sensitive

Description

With this option you tell the assembler not to distinguish between uppercase and lowercase characters. By default the assembler considers uppercase and lowercase characters as different characters.

Example

When assembling case insensitive, the label `LabelName` is the same label as `labelname`.

```
ccmcs --case-insensitive test.asm
```

Related information

Assembler option `--case-insensitive`

Assembler control `$CASE`

Control program option: **--check**

Menu entry

-

Command line syntax

--check

Description

With this option you can check the source code for syntax errors, without generating code. This saves time in developing your application because the code will not actually be compiled.

The compiler/assembler reports any warnings and/or errors.

This option is available on the command line only.

Related information

C compiler option **--check** (Check syntax)

Assembler option **--check** (Check syntax)

Control program option: `--control-flow-info`

Menu entry

1. Select **C Compiler » Debugging**.
2. Enable the option **Generate control flow information**.

Command line syntax

```
--control-flow-info
```

Description

Control flow information

With this option the compiler adds control flow information to the output file. The compiler generates a `.debug_control_flow` section which describes the basic blocks and their relations. This information can be used for code coverage analysis on optimized code.

Example

```
ccmcs --control-flow-info test.c
```

Related information

Section 6.4.2, *HLL Dump Output Format*

Control program option `--debug-info` (Debug information)

Control program option: **--core**

Menu entry

1. Expand **C/C++ Build** and select **Processor**.
2. From the **Processor Selection** list, select a processor or select **User defined ...**

Command line syntax

`--core=core`

You can specify the following *core* arguments:

mcs1.0	MCS v1.0 core
mcs2.0	MCS v2.0 core
mcs3.0	MCS v3.0 core
mcs3.1	MCS v3.1 core

Default: **mcs3.1**

Description

With this option you specify the core architecture for a target processor for which you create your application. If you use Eclipse or the control program, the MCS toolset derives the core from the processor you selected. When the default core (**mcs3.1**) is used, the macro `__CORE_MCS31__` is defined in the C source file.

Note that the C compiler only supports cores **mcs3.0** and **mcs3.1**. The assembler and linker support all cores.

With `--core=mcs1.0`, you tell the assembler that the assembly file contains instructions for the MCS v1.0 core.

With `--core=mcs2.0`, you tell the assembler that the assembly file contains instructions for the MCS v2.0 core.

With `--core=mcs3.0`, the compiler can generate MCS v3.0 instructions in the assembly file. The macro `__CORE_MCS30__` is defined in the C source file.

With `--core=mcs3.1`, the compiler can generate MCS v3.1 instructions in the assembly file. The macro `__CORE_MCS31__` is defined in the C source file.

Example

Select an MCS v3.0 core:

```
ccmcs --core=mcs3.0 test.c
```

Related information

Control program option **--cpu** (Select processor)

Control program option: **--cpu (-C)**

Menu entry

1. Expand **C/C++ Build** and select **Processor**.
2. From the **Processor selection** list, select a processor or select **User defined ...**

Command line syntax

`--cpu=id | name | cpu`

`-Cid | name | cpu`

Description

With this option you define the target processor for which you create your application. You can specify a full processor *name*, like TC39xB, or a base *CPU* name, like tc39xb or its unique *id*, like tc39xb.

The standard list of supported processors is defined in the file `processors.xml`. This file defines for each processor its full name (for example, TC39xB), its ID, the base CPU name (for example, tc39xb) and the core settings (for example, mcs). To show a list of all supported processors you can use option **--cpu-list**.

The control program reads the file `processors.xml`. The lookup sequence for names specified to this option is as follows:

1. match with the 'id' attribute in `processors.xml` (case insensitive, for example `tc39xb`)
2. if none matched, match with the 'name' attribute in `processors.xml` (case insensitive, for example `TC39xB`)
3. if still none matched, match any of the base CPU names (the 'cpu' attribute in `processors.xml`, for example `tc39xb`). If multiple processors exist with the same base CPU, a warning will be issued and the first one is selected.
4. if still none matched, the control program issues a fatal error.

The preferred use of the option **--cpu**, is to specify an ID because that is always a unique name. For example, **--cpu=tc39xb**. The control program will lookup this processor name in the file `processors.xml`. The control program passes the options to the underlying tools. For example, **-D__CPU__=tc39xb** **-D__CPU_TC39XB__** to the C compiler and assembler, or **-dtc39xb.lsl -D__CPU__=tc39xb** **-D__PROC_TC39XB__ --core=mcs00** to the linker.

Example

To generate the file `test.elf` for the TC39xB processor, enter:

```
ccmcs --cpu=tc39xb test.c
```

Related information

Control program option **--cpu-list** (Show list of processors)

Control program option **--lsl-core** (Specify LSL core)

Control program option **--processors** (Read additional processor definitions)

Control program option: `--cpu-list`

Menu entry

-

Command line syntax

`--cpu-list`[=*pattern*]

Description

With this option the control program shows a list of supported processors as defined in the file `processors.xml`. This can be useful when you want to select a processor name or id for the `--cpu` option.

The *pattern* works similar to the UNIX `grep` utility. You can use it to limit the output list.

Example

To show a list of all processors, enter:

```
ccmcs --cpu-list
```

To show all processors of the mcs3.1 core, enter:

```
ccmcs --cpu-list=mcs3.1
```

```
--- ~/cmcs/etc/processors.xml ---
  id          name          CPU          core
  userdef16x  User defined TriCore 1.6.2 userdef162   mcs3.1
  tc38x       TC38x          tc38x        mcs3.1
  tc39x       TC39x          tc39x        mcs3.1
  tc39xb      TC39xB         tc39xb       mcs3.1
```

Related information

Control program option `--cpu` (Select processor)

Control program option: `--create (-c)`

Menu entry

-

Command line syntax

```
--create [=stage]
```

```
-c [stage]
```

You can specify the following stages:

relocatable	l	Stop after the files are linked to a linker object file (.out)
mil	m	Stop after C files are compiled to MIL (.mil)
object	o	Stop after the files are assembled to objects (.o)
assembly	s	Stop after C files are compiled to assembly (.src)

Default (without flags): `--create=object`

Description

Normally the control program generates an absolute object file of the specified output format from the file you supplied as input. With this option you tell the control program to stop after a certain number of phases.

Example

To generate the object file `test.o`:

```
ccmcs --create test.c
```

The control program stops after the file is assembled. It does not link nor locate the generated output.

Related information

Linker option `--link-only` (Link only, no locating)

Control program option: **--debug-info (-g)**

Menu entry

1. Select **C Compiler » Debugging**.
2. To **generate symbolic debug information**, select **Default**, **Small set** or **Full**.
To disable the generation of debug information, select **None**.

Command line syntax

`--debug-info[=suboption]`

`-g[suboption]`

You can set the following suboptions:

small	1 c	Emit small set of debug information.
default	2 d	Emit default symbolic debug information.
all	3 a	Emit full symbolic debug information.

Default: `--debug-info` (same as `--debug-info=default`)

Description

With this option you tell the control program to include debug information in the generated object file.

The control program passes the option `-gsuboption` to the C compiler and calls the assembler with `-gsl`.

Related information

C compiler option `--debug-info` (Generate symbolic debug information)

Assembler option `--debug-info` (Generate symbolic debug information)

Control program option: --define (-D)

Menu entry

1. Select **Assembler » Preprocessing**.

The Defined symbols box right-below shows the symbols that are currently defined.

2. To define a new symbol, click on the **Add** button in the **Defined symbols** box.
3. Type the symbol definition (for example, demo=1)

Use the **Edit** and **Delete** button to change a macro definition or to remove a macro from the list.

Command line syntax

```
--define=macro_name[=macro_definition]
```

```
-Dmacro_name[=macro_definition]
```

Description

With this option you can define a macro and specify it to the preprocessor. If you only specify a macro name (no macro definition), the macro expands as '1'.

You can specify as many macros as you like. Simply use the **Add** button to add new macro definitions.

On the command line, use the option **--define (-D)** multiple times. If the command line exceeds the limit of the operating system, you can define the macros in an option file which you then must specify to the assembler with the option **--option-file (-f) file**.

Defining macros with this option (instead of in the assembly source) is, for example, useful to assembly conditional assembly source as shown in the example below.

The control program passes the option **--define (-D)** to the assembler.

Make sure you do not use a reserved keyword as a macro name, as this can lead to unexpected results.

Example

Consider the following C program with conditional code to compile a demo program and a real program:

```
void main( void )
{
  #if DEMO
    demo_func(); /* compile for the demo program */
  #else
    real_func(); /* compile for the real program */
  #endif
}
```

TASKING VX-toolset for MCS User Guide

```
#endif  
}
```

You can now use a macro definition to set the DEMO flag:

```
ccmcs --define=DEMO test.c  
ccmcs --define=DEMO=1 test.c
```

Note that both invocations have the same effect.

The next example shows how to define a macro with arguments. Note that the macro name and definition are placed between double quotes because otherwise the spaces would indicate a new option.

```
ccmcs --define="MAX(A,B)=((A) > (B) ? (A) : (B))" test.c
```

Related information

Control program option **--undefine** (Remove preprocessor macro)

Control program option **--option-file** (Specify an option file)

Control program option: `--dep-file`

Menu entry

-

Command line syntax

```
--dep-file[=file]
```

Description

With this option you tell the compiler to generate dependency lines that can be used in a Makefile. In contrast to the option `--preprocess=+make`, the dependency information will be generated in addition to the normal output file.

By default, the information is written to a file with extension `.d` (one for every input file). When you specify a filename, all dependencies will be combined in the specified file.

Example

```
ccmcs --dep-file=test.dep -t test.c
```

The compiler compiles the file `test.c`, which results in the output file `test.src`, and generates dependency lines in the file `test.dep`.

Related information

Control program option `--preprocess=+make` (Generate dependencies for make)

Control program option: --diag

Menu entry

1. From the **Window** menu, select **Show View » Other » TASKING » Problems**.

The Problems view is added to the current perspective.

2. In the Problems view right-click on a message.

A popup menu appears.

3. Select **Detailed Diagnostics Info**.

A dialog box appears with additional information.

Command line syntax

```
--diag=[format:]{all | nr,...}
```

You can set the following output formats:

html	HTML output.
rtf	Rich Text Format.
text	ASCII text.

Default format: text

Description

With this option you can ask for an extended description of error messages in the format you choose. The output is directed to stdout (normally your screen) and in the format you specify. You can specify the following formats: **html**, **rtf** or **text** (default). To create a file with the descriptions, you must redirect the output.

With the suboption **all**, the descriptions of all error messages are given. If you want the description of one or more selected error messages, you can specify the error message numbers, separated by commas.

Example

To display an explanation of message number 103, enter:

```
ccmcs --diag=103
```

This results in message 103 with explanation.

To write an explanation of all errors and warnings in HTML format to file `ccerrors.html`, use redirection and enter:

```
ccmcs --diag=html:all > ccerrors.html
```

Related information

-

Control program option: `--dry-run (-n)`

Menu entry

-

Command line syntax

`--dry-run`

`-n`

Description

With this option you put the control program in verbose mode. The control program prints the invocations of the tools it would use to process the files without actually performing the steps.

Related information

Control program option `--verbose` (Verbose output)

Control program option: `--endianness`

Menu entry

1. Select **Global Options**.
2. Specify the **Endianness:Little-endian mode** or **Big-endian mode**.

Command line syntax

`--endianness=endianness`

`-B`

`--big-endian`

You can specify the following *endianness*:

big	b	Big endian
little	l	Little endian (default)

Description

With this option the control program tells the assembler and linker what the endianness is of the host CPU. By default, the assembler and linker generate code for a little-endian target (least significant byte of a word at lowest byte address). With `--endianness=big` the assembler and linker generate code for a big-endian target (most significant byte of a word at lowest byte address). `-B` is an alias for option `--endianness=big`.

Related information

-

Control program option: **--error-file**

Menu entry

-

Command line syntax

--error-file

Description

With this option the control program tells the compiler, assembler and linker to redirect diagnostic messages to a file.

The error file will be named after the output file with extension `.err` (for compiler) or `.ers` (for assembler). For the linker, the error file is `lmcs.elk`.

Example

To write diagnostic messages to error files instead of `stderr`, enter:

```
ccmcs --error-file -t test.c
```

Related information

Control Program option **--warnings-as-errors** (Treat warnings as errors)

Control program option: `--error-limit`

Menu entry

1. Select **C Compiler » Diagnostics**.
2. Enter a value in the **Maximum number of emitted errors** field.

Command line syntax

```
--error-limit=number
```

Default: 42

Description

With this option you limit the number of error messages in one invocation to the specified number. When the limit is exceeded, the control program aborts with fatal error message F105. Warnings and informational messages are not included in the count. When 0 (zero) or a negative number is specified, the control program emits all errors. Without this option the maximum number of errors is 42. The control program also passes this option to the C compiler, assembler and linker.

Related information

[Section 3.7, C Compiler Error Messages](#)

Control program option: `--extended-registers`

Menu entry

1. Select **C Compiler » Code Generation**.
2. Enable the option **Use extended register set**.

Command line syntax

`--extended-registers`

Description

The extended register set extends the registers of the current MCS channel with the registers of the next MCS channel. By default the extended register set is disabled. You can use this option to enable the extended register set. The compiler enables RS0..RS7, whereas the assembler enables RS0..RS7, DSTAT, GMI0 and GMI1

Related information

-

Control program option: `--format`

Menu entry

1. Select **Linker » Output Format**.
2. Enable the option **Generate Intel Hex format file** and/or **Generate S-records file** and/or **Generate C array file**.
3. Optionally, specify the **Size of addresses**.

Eclipse always uses the project name as the basename for the output file.

Command line syntax

`--format=format`

You can specify the following formats:

ELF	ELF/DWARF
IHEX	Intel Hex
SREC	Motorola S-records
CARR	C array

Description

With this option you specify the output format for the resulting (absolute) object file. The default output format is ELF/DWARF, which can directly be used by the debugger.

If you choose IHEX or SREC, you can additionally specify the address size of the chosen format (option `--address-size`).

If you choose CARR, the linker generates an output file for each memory chip in the C array format. The C array format contains the generated machine code in the form of C code. For more information see [Section 12.4, C Array Format](#).

Example

To generate a Motorola S-record output file:

```
ccmcs --format=SREC test1.c test2.c --output=test.sre
```

To generate C array output files (.c and .h):

```
ccmcs --format=CARR test1.c test2.c --output=test
```

Related information

Control program option `--address-size` (Set address size for linker IHEX/SREC files)

TASKING VX-toolset for MCS User Guide

Control program option **--output** (Output file)

Linker option **--chip-output** (Generate an output file for each chip)

Control program option: `--fp-model`

Menu entry

1. Select **C Compiler » Floating-Point**.
2. Make a selection from the **Floating-point model** list.
3. If you selected **Custom**, enable one or more individual options.

Command line syntax

`--fp-model=flags`

You can set the following flags:

+/-contract	c/C	allow expression contraction
+/-float	f/F	treat 'double' as 'float'
+/-fastlib	l/L	allow less precise library functions
+/-nonan	n/N	allow optimizations to ignore NaN/Inf
+/-rewrite	r/R	allow expression rewriting
+/-trap	t/T	support trapping on exceptions
+/-negzero	z/Z	ignore sign of -0.0
	0	alias for <code>--fp-model=CFLNRtZ</code> (strict)
	1	alias for <code>--fp-model=cFLNRTZ</code> (precise)
	2	alias for <code>--fp-model=cFlnrTz</code> (fast double)
	3	alias for <code>--fp-model=cflnrTz</code> (fast single)

Default: `--fp-model=cflnrTz`

Description

With this option you select the floating-point execution model.

With `--fp-model=+contract` you allow the compiler to contract multiple float operations into a single operation, with different rounding results. A possible example is fused multiply-add.

With `--fp-model=+float` you tell the compiler to treat variables and constants of type `double` as `float`. Because the `float` type takes less space, execution speed increases and code size decreases, both at the cost of less precision. The control program automatically selects the correct libraries.

With `--fp-model=+fastlib` you allow the compiler to select faster but less accurate library functions for certain floating-point operations. With `--fp-model=-fastlib` more precise library functions are used and the compiler defines the macro `__PRECISE_LIB_FP__`, which is used in `math.h`.

TASKING VX-toolset for MCS User Guide

With **--fp-model=+nonan** you allow the compiler to ignore NaN or Inf input values. An example is to replace multiply by zero with zero.

With **--fp-model=+rewrite** you allow the compiler to rewrite expressions by reassociating. This might result in rounding differences and possibly different exceptions. An example is to rewrite $(a*c)+(b*c)$ as $(a+b)*c$.

With **--fp-model=+trap** operations trap on floating-point exceptions. By default the control program uses the non-trapping versions of the floating-point library (`libfp.a`). With this option you tell the control program to use the trapping versions of the floating-point library (`libfpt.a`).

If you use the trapping floating-point library, exceptional floating-point cases are intercepted and can be handled separately by an application defined exception handler. Using this library decreases the execution speed of your application.

With **--fp-model=+negzero** you allow the compiler to ignore the sign of -0.0 values. An example is to replace $(a-a)$ by zero.

Related information

Pragmas `STDC_FP_CONTRACT`, `fp_negzero`, `fp_nonan` and `fp_rewrite` in [Section 1.7, Pragmas to Control the Compiler](#).

Control program option: `--global-type-checking`

Menu entry

1. Select **C Compiler » Diagnostics**.
2. Enable the option **Perform global type checking on C code**.

Command line syntax

`--global-type-checking`

Description

The C compiler already performs type checking within each module. Use this option when you want the linker to perform type checking between modules. The control program passes this option to both the C compiler and the linker.

Related information

-

Control program option: --help (-?)

Menu entry

-

Command line syntax

`--help[=item]`

`-?`

You can specify the following argument:

options	Show extended option descriptions
----------------	-----------------------------------

Description

Displays an overview of all command line options. When you specify the argument **options** you can list detailed option descriptions.

Example

The following invocations all display a list of the available command line options:

```
ccmcs -?  
ccmcs --help  
ccmcs
```

To see a detailed description of the available options, enter:

```
ccmcs --help=options
```

Related information

-

Control program option: `--include-directory (-I)`

Menu entry

1. Select **Assembler » Include Paths**.

The Include paths box shows the directories that are added to the search path for include files.

2. To define a new directory for the search path, click on the **Add** button in the **Include paths** box.
3. Type or select a path.

Use the **Edit** and **Delete** button to change a path or to remove a path from the list.

Command line syntax

```
--include-directory=path,...
```

```
-Ipath,...
```

Description

With this option you can specify the path where your include files are located. A relative path will be relative to the current directory.

The control program passes this option to the compiler and the assembler.

Example

Suppose that the C source file `test.c` contains the following lines:

```
#include <stdio.h>
#include "myinc.h"
```

You can call the control program as follows:

```
cc87 --include-directory=myinclude test.c
```

First the compiler looks for the file `stdio.h` in the directory `myinclude` relative to the current directory. If it was not found, the compiler searches in the environment variable and then in the default include directory.

The compiler now looks for the file `myinc.h` in the directory where `test.c` is located. If the file is not there the compiler searches in the directory `myinclude`. If it was still not found, the compiler searches in the environment variable and then in the default include directory.

Related information

[C compiler option `--include-directory`](#) (Add directory to include file search path)

[C compiler option `--include-file`](#) (Include file at the start of a compilation)

TASKING VX-toolset for MCS User Guide

Assembler option **--include-directory** (Add directory to include file search path)

Assembler option **--include-file** (Include file at the start of the input file)

Control program option: --include-file (-H)

Menu entry

1. Select **C/C++ Compiler » Preprocessing**.

The Pre-include files box shows the files that are currently included before the compilation starts.

2. To define a new file, click on the **Add** button in the **Pre-include files** box.
3. Type the full path and file name or select a file.

Use the **Edit** and **Delete** button to change a file name or to remove a file from the list.

Command line syntax

```
--include-file=file,...
```

```
-Hfile,...
```

Description

With this option you include one or more extra files at the beginning of each C source file, before other includes. This is the same as specifying `#include "file"` at the beginning of *each* of your C sources.

Example

```
ccmcs --include-file=stdio.h test1.c test2.c
```

The file `stdio.h` is included at the beginning of both `test1.c` and `test2.c`.

Related information

C compiler option **--include-directory** (Add directory to include file search path)

C compiler option **--include-file** (Include file at the start of a compilation)

Control program option: `--instruction-set`

Menu entry

1. Select **C Compiler » Code Generation**.
2. Enable or disable the option **Allow divide/modulo instructions**.
3. Enable or disable the option **Allow multiply instructions**.

Command line syntax

`--instruction-set=flags`

You can set the following flags:

+/-divide	d/D	allow the use of divide/modulo instructions
+/-multiply	m/M	allow the use of multiply instructions

Default: `--instruction-set=dm`

Description

With this option you can select which instructions the compiler can use for code generation and as such which instructions the assembler accepts. When the compiler is not allowed to use an instruction a run-time library call is used instead. When the selected core forbids the use of an instruction it will never be used, even when enabled by this option.

With `--instruction-set=+divide` you allow the compiler and assembler to use the DIVU and DIVS instructions. These instruction are used to generate code for the divide (/) and modulo (%) operations.

With `--instruction-set=+multiply` you allow the compiler and assembler to use the MULU and MULS instructions.

If one or both of the instructions are disabled, the control program specifies the libraries from the `nm` directory to the linker.

-

Control program option: `--iso`

Menu entry

1. Select **C Compiler » Language**.
2. From the **Comply to C standard** list, select **ISO C99**, **ISO C11**, or **ISO C90**.

Command line syntax

```
--iso={90 | 99 | 11}
```

Default: `--iso=11`

Description

With this option you select the ISO C standard. C90 is also referred to as the "ANSI C standard". C99 refers to the ISO/IEC 9899:1999 (E) standard. C11 refers to the ISO/IEC 9899:2011 (E) standard. C11 is the default.

Independent of the chosen ISO C standard, the control program always links libraries with C11 support.

Example

To select the ISO C99 standard on the command line:

```
ccmcsc --iso=99 test.c
```

Related information

C compiler option `--iso` (ISO C standard)

Control program option: **--keep-output-files (-k)**

Menu entry

Eclipse *always* removes generated output files when an error occurs.

Command line syntax

--keep-output-files

-k

Description

If an error occurs during the compilation, assembling or linking process, the resulting output file may be incomplete or incorrect. With this option you keep the generated output files when an error occurs.

By default the control program removes generated output files when an error occurs. This is useful when you use the make utility. If the erroneous files are not removed, the make utility may process corrupt files on a subsequent invocation.

Use this option when you still want to use the generated files. For example when you know that a particular error does not result in a corrupt file, or when you want to inspect the output file, or send it to Altium support.

The control program passes this option to the compiler, assembler and linker.

Example

```
ccmcs --keep-output-files test.c
```

When an error occurs during compiling, assembling or linking, the erroneous generated output files will not be removed.

Related information

C compiler option **--keep-output-files**

Assembler option **--keep-output-files**

Linker option **--keep-output-files**

Control program option: `--keep-temporary-files (-t)`

Menu entry

1. Select **Global Options**.
2. Enable the option **Keep temporary files**.

Command line syntax

```
--keep-temporary-files
```

```
-t
```

Description

By default, the control program removes intermediate files like the `.src` file (result of the compiler phase) and the `.o` file (result of the assembler phase).

With this option you tell the control program to keep temporary files it generates during the creation of the absolute object file.

Example

```
ccmcs --keep-temporary-files test.c
```

The control program keeps all intermediate files it generates while creating the absolute object file `test.elf`.

Related information

-

Control program option: **--library (-l)**

Menu entry

1. Select **Linker » Libraries**.

The Libraries box shows the list of libraries that are linked with the project.

2. To add a library, click on the **Add** button in the **Libraries** box.
3. Type or select a library (including its path).
4. Optionally, disable the option **Link default libraries**.

Use the **Edit** and **Delete** button to change a library name or to remove a library from the list.

Command line syntax

--library=*name*

-l*name*

Description

With this option you tell the linker via the control program to use system library `libname.a`, where *name* is a string. The linker first searches for system libraries in any directories specified with **--library-directory**, then in the directories specified with the environment variables `LIBMCS` / `LIBMCS2_0` / `LIBMCS3_0` / `LIBMCS3_1`, unless you used the option **--ignore-default-library-path**.

Example

To search in the system library `libc.a` (C library):

```
ccmcs test.o mylib.a --library=c
```

The linker links the file `test.o` and first looks in library `mylib.a` (in the current directory only), then in the system library `libc.a` to resolve unresolved symbols.

Related information

Control program option **--no-default-libraries** (Do not link default libraries)

Control program option **--library-directory** (Additional search path for system libraries)

Section 5.3, *Linking with Libraries*

Chapter 10, *Libraries*

Control program option: **--library-directory (-L) / --ignore-default-library-path**

Menu entry

1. Select **Linker » Libraries**.

The Library search path box shows the directories that are added to the search path for library files.

2. To define a new directory for the search path, click on the **Add** button in the **Library search path** box.
3. Type or select a path.

Use the **Edit** and **Delete** button to change a path or to remove a path from the list.

Command line syntax

```
--library-directory=path,...
-Lpath,...

--ignore-default-library-path
-L
```

Description

With this option you can specify the path(s) where your system libraries, specified with the option **--library (-L)**, are located. If you want to specify multiple paths, use the option **--library-directory** for each separate path.

The default path is $\$(PRODDIR)\lib\{mcs30|mcs31}\{be|le}$.

If you specify only **-L** (without a pathname) or the long option **--ignore-default-library-path**, the linker will not search the default path and also not in the paths specified in the environment variables `LIBMCS / LIBMCS2_0 / LIBMCS3_0 / LIBMCS3_1`. So, the linker ignores steps 2 and 3 as listed below.

The priority order in which the linker searches for system libraries specified with the option **--library (-L)** is:

1. The path that is specified with the option **--library-directory**.
2. The path that is specified in the environment variables `LIBMCS / LIBMCS2_0 / LIBMCS3_0 / LIBMCS3_1`.
3. The default directory $\$(PRODDIR)\lib\{mcs30|mcs31}\{be|le}$.

Example

Suppose you call the control program as follows:

TASKING VX-toolset for MCS User Guide

```
ccmcs test.c --library-directory=c:\mylibs --library=c
```

First the linker looks in the directory `c:\mylibs` for library `libc.a` (this option). If it does not find the requested libraries, it looks in the directory that is set with the environment variables `LIBMCS` / `LIBMCS2_0` / `LIBMCS3_0` / `LIBMCS3_1`. Then the linker looks in the default directory `$(PRODDIR)\lib\{mcs30|mcs31}\{be|le}` for libraries.

Related information

Control program option **--library** (Link system library)

Section 5.3.1, *How the Linker Searches Libraries*

Control program option: **--link-only**

Menu entry

-

Command line syntax

--link-only

Description

With this option you suppress the locating phase. The linker stops after linking and informs you about unresolved references.

Related information

Control program option **--create=relocatable (-cl)** (Stop after linking)

Linker option **--link-only** (Link only, no locating)

Control program option: **--list-files**

Menu entry

-

Command line syntax

--list-files[=*file*]

Default: no list files are generated

Description

With this option you tell the assembler via the control program to generate a list file for each specified input file. A list file shows the generated object code and the relative addresses. Note that the assembler generates a relocatable object file with relative addresses.

With the optional *file* you can specify a name for the list file. This is only possible if you specify only one input file to the control program. If you do not specify a file name, or you specify more than one input file, the control program names the generated list file(s) after the specified input file(s) with extension `.lst`.

Note that object files and library files are not counted as input files.

Related information

Assembler option **--list-file** (Generate list file)

Assembler option **--list-format** (Format list file)

Control program option: `--lsl-core`

Menu entry

1. Expand **C/C++ Build** and select **Processor**.
2. From the **Select core** list, select a processor core.

Command line syntax

```
--lsl-core=MCS-core
```

Depending on the used processor, you can specify the following MCS cores:

mcs00	MCS core 0
mcs01	MCS core 1
mcs02	MCS core 2
mcs03	MCS core 3
mcs04	MCS core 4
mcs05	MCS core 5
mcs06	MCS core 6
mcs07	MCS core 7
mcs08	MCS core 8
mcs09	MCS core 9

Default: **mcs00**

Description

With this option you can specify the LSL core architecture the code is intended for. For example, the file `tc39xb.lsl` in the `include.lsl` directory, contains a description of derivative `tc39xb` and the supported MCS cores.

Example

To link objects for the MCS core `mcs01`, enter:

```
ccmcs --cpu=tc39xb --lsl-core=mcs01 -t test.c
```

This results in the following invocation of the tools:

```
+ cmmc --instruction-set=dm -D__CPU__=tc39xb
  -D__CPU_TC39XB__ --core=mcs3.1 --fp-model=cFlnrTz -o test.src test.c
+ asmcs --instruction-set=dm -D__CPU__=tc39xb
  -D__CPU_TC39XB__ --core=mcs3.1 --endianness=little -o test.o test.src
+ lmcs -o test.out -d tc39xb.lsl --core=mcs01
  --endianness=little -D__CPU__=tc39xb -D__PROC_TC39XB__
```

TASKING VX-toolset for MCS User Guide

```
--link-only -D__LINKONLY__ --map-file test.o  
"-Lpath\lib\mcs31\le" -lc -lfp -lrt
```

Related information

Linker option **--core** (Specify LSL core)

Control program option: `--lsl-file (-d)`

Menu entry

An LSL file can be generated when you create your project in Eclipse:

1. From the **File** menu, select **File » New » TASKING MCS C Project**.

The New C Project wizard appears.

2. Fill in the project settings in each dialog and click **Next >** until the **MCS Project Settings** appear.
3. Enable the option **Add linker script file to the project** and click **Finish**.

Eclipse creates your project and the file `project.lsl` in the project directory.

The LSL file can be specified in the Properties dialog:

1. Select **Linker » Script File**.
2. Specify a LSL file in the **Linker script file (.lsl)** field.

Command line syntax

```
--lsl-file=file,...
```

```
-dfile,...
```

Description

A linker script file contains vital information about the core for the locating phase of the linker. A linker script file is coded in LSL and contains the following types of information:

- the architecture definition describes the core's hardware architecture.
- the memory definition describes the physical memory available in the system.
- the section layout definition describes how to locate sections in memory.

With this option you specify a linker script file via the control program to the linker. If you do not specify this option, the linker uses a default script file. You can specify the existing file `target.lsl` or the name of a manually written linker script file. You can use this option multiple times. The linker processes the LSL files in the order in which they appear on the command line.

Related information

[Section 5.7, Controlling the Linker with a Script](#)

Control program option: **--make-target**

Menu entry

-

Command line syntax

--make-target=*name*

Description

With this option you can overrule the default target name in the make dependencies generated by the options **--preprocess+=make** (**-Em**) and **--dep-file**. The default target name is the basename of the input file, with extension `.o`.

Example

```
ccmcs --preprocess+=make --make-target=./mytarget.o test.c
```

The compiler generates dependency lines with the default target name `./mytarget.o` instead of `test.o`.

Related information

Control program option **--preprocess+=make** (Generate dependencies for make)

Control program option **--dep-file** (Generate dependencies in a file)

Control program option: `--meminit`

Menu entry

1. Select **Global Options**.
2. Select the **Initialization mode**.

Command line syntax

`--meminit=mode`

You can specify the following modes:

cpu	Initialization is done by a CPU
mcs	Self contained initialization from ROM
none	The program is loaded directly into RAM

Description

With this option you can specify the initialization mode for the MCS memory. Initialization by CPU is the default.

With `--meminit=cpu`, initialization of MCS memory is done by the CPU. The following applies:

- If the MCS is reset and the CPU is not reset at the same time, the MCS memory image is, or may be, incorrect.
- The start-up code of the MCS does not initialize the MCS memory.
- The user provided initialization code is the CPU initialization code.
- The control program calls the linker with the options `--link-only` and `-D__LINKONLY__`.

With `--meminit=mcs`, initialization is done by the MCS. This is the case for an MCS with its own ROM. The MCS can be reset and its memory will be re-initialized correctly. The following applies:

- The start-up code of the MCS initializes the MCS memory by copying ROM to RAM and clearing BSS sections.

With `--meminit=none`, the MCS does not initialize its memory. You can use this option when you want to debug your program with the simulator. The following applies:

- If the MCS is soft reset, the MCS global data is not re-initialized.
- The start-up code of the MCS does not initialize the MCS memory.
- The user provided initialization code is empty.
- The control program calls the linker with the options `--non-romable`, `--user-provided-initialization-code` and `--no-rom-copy`.

TASKING VX-toolset for MCS User Guide

- The simulator clears all memory, implicitly clearing all BSS sections.
- The simulator initializes RAM data sections, because initialization data is defined in RAM data sections as a consequence of the linker option **---no-rom-copy**.

Example

To initialize MCS memory from ROM:

```
ccmcs --meminit=mcs test.c
```

Related information

Control program option **--address-size** (Set address size for linker IHEX/SREC files)

Control program option **--output** (Output file)

Linker option **--chip-output** (Generate an output file for each chip)

Control program option: `--no-default-libraries`

Menu entry

1. Select **Linker » Libraries**.
2. Disable the option **Link default libraries**.

Command line syntax

`--no-default-libraries`

Description

By default the control program specifies the standard C libraries (C99) and run-time library to the linker. With this option you tell the control program not to specify the standard C libraries and run-time library to the linker.

In this case you must specify the libraries you want to link to the linker with the option `--library=library_name` or pass the libraries as files on the command line. The control program recognizes the option `--library (-l)` as an option for the linker and passes it as such.

Example

```
ccmcs --no-default-libraries test.c
```

The control program does not specify any libraries to the linker. In normal cases this would result in unresolved externals.

To specify your own libraries (`libc.a`) and avoid unresolved externals:

```
ccmcs --no-default-libraries --library=c test.c
```

Related information

Control program option `--library` (Link system library)

Section 5.3.1, *How the Linker Searches Libraries*

Control program option: **--no-map-file**

Menu entry

1. Select **Linker » Map File**.
2. Disable the option **Generate map file**.

Command line syntax

--no-map-file

Description

By default the control program tells the linker to generate a linker map file.

A linker map file is a text file that shows how the linker has mapped the sections and symbols from the various object files (.o) to the linked object file. A locate part shows the absolute position of each section. External symbols are listed per space with their absolute address, both sorted on symbol and sorted on address.

With this option you prevent the generation of a map file.

Related information

-

Control program option: `--no-warnings (-w)`

Menu entry

1. Select **C Compiler » Diagnostics**.

The Suppress C compiler warnings box shows the warnings that are currently suppressed.

2. To suppress a warning, click on the **Add** button in the **Suppress C compiler warnings** box.
3. Enter the numbers, separated by commas or as a range, of the warnings you want to suppress (for example 537, 538). Or you can use the **Add** button multiple times.
4. To suppress all warnings, enable the option **Suppress all warnings**.

Use the **Edit** and **Delete** button to change a warning number or to remove a number from the list.

Command line syntax

```
--no-warnings [=number[-number], ...]
```

```
-w [number[-number], ...]
```

Description

With this option you can suppresses all warning messages for the various tools or specific control program warning messages.

On the command line this option works as follows:

- If you do not specify this option, all warnings are reported.
- If you specify this option but without numbers, all warnings of all tools are suppressed.
- If you specify this option with a number or a range, only the specified control program warnings are suppressed. You can specify the option `--no-warnings=number` multiple times.

Example

To suppress all warnings for all tools, enter:

```
ccmcs test.c --no-warnings
```

Related information

Control program option `--warnings-as-errors` (Treat warnings as errors)

Control program option: **--option-file (-f)**

Menu entry

-

Command line syntax

--option-file=*file*,...

-f *file*,...

Description

This option is primarily intended for command line use. Instead of typing all options on the command line, you can create an option file which contains all options and flags you want to specify. With this option you specify the option file to the control program.

Use an option file when the command line would exceed the limits of the operating system, or just to store options and save typing.

You can specify the option **--option-file** multiple times.

Format of an option file

- Multiple arguments on one line in the option file are allowed.
- To include whitespace in an argument, surround the argument with single or double quotes.
- If you want to use single quotes as part of the argument, surround the argument by double quotes and vice versa:

```
"This has a single quote ' embedded"
```

```
'This has a double quote " embedded'
```

```
'This has a double quote " and a single quote ''' embedded"
```

- When a text line reaches its length limit, use a \ to continue the line. Whitespace between quotes is preserved.

```
"This is a continuation \  
line"
```

```
-> "This is a continuation line"
```

- It is possible to nest command line files up to 25 levels.

Example

Suppose the file `myoptions` contains the following lines:

```
--debug-info  
--define=DEMO=1  
test.c
```

Specify the option file to the control program:

```
ccmcs --option-file=myoptions
```

This is equivalent to the following command line:

```
ccmcs --debug-info --define=DEMO=1 test.c
```

Related information

-

Control program option: **--output (-o)**

Menu entry

Eclipse always uses the project name as the basename for the output file.

Command line syntax

```
--output=file
```

```
-o file
```

Description

By default, the control program generates a file with the same basename as the first specified input file. With this option you specify another name for the resulting absolute object file.

The default output format is ELF/DWARF, but you can specify another output format with option **--format**.

Example

```
ccmcs test.c prog.c
```

The control program generates an ELF/DWARF object file (default) with the name `test.elf`.

To generate the file `result.elf`:

```
ccmcs --output=result.elf test.c prog.c
```

Related information

Control program option **--format** (Set linker output format)

Linker option **--output** (Output file)

Linker option **--chip-output** (Generate an output file for each chip)

Control program option: --pass (-W)

Menu entry

1. Select **C Compiler » Miscellaneous** or **Assembler » Miscellaneous** or **Linker » Miscellaneous**.
2. Add an option to the **Additional options** field.

*Be aware that the options in the option file are added to the options you have set in the other pages. Only in extraordinary cases you may want to use them in combination. The assembler options are preceded by **-Wa** and the linker options are preceded by **-Wl**. For the C options you have to do this manually.*

Command line syntax

<code>--pass-assembler=option</code>	<code>-Waoption</code>	Pass option directly to the assembler
<code>--pass-c=option</code>	<code>-Wcoption</code>	Pass option directly to the C compiler
<code>--pass-linker=option</code>	<code>-Wloption</code>	Pass option directly to the linker

Description

With this option you tell the control program to call a tool with the specified option. The control program does not use or interpret the option itself, but specifies it directly to the tool which it calls.

Example

To pass the option **--verbose** directly to the linker, enter:

```
ccmcs --pass-linker=--verbose test.c
```

Related information

-

Control program option: `--preprocess (-E) / --no-preprocessing-only`

Menu entry

1. Select **C Compiler » Preprocessing**.
2. Enable the option **Store preprocessor output in <file>.pre**.
3. (Optional) Enable the option **Keep comments in preprocessor output**.
4. (Optional) Enable the option **Keep #line info in preprocessor output**.

Command line syntax

`--preprocess [=flags]`

`-E[flags]`

`--no-preprocessing-only`

You can set the following flags:

+/-comments	c/C	keep comments
+/-includes	i/I	generate a list of included source files
+/-list	l/L	generate a list of macro definitions
+/-make	m/M	generate dependencies for make
+/-noline	p/P	strip #line source position information

Default: `-ECILMP`

Description

With this option you tell the compiler to preprocess the C source. The C compiler sends the preprocessed output to the file `name.pre` (where `name` is the name of the C source file to compile). Eclipse also compiles the C source.

On the command line, the control program stops after preprocessing. If you also want to compile the C source you can specify the option `--no-preprocessing-only`. In this case the control program calls the compiler twice, once with option `--preprocess` and once for a regular compilation.

With `--preprocess=+comments` you tell the preprocessor to keep the comments from the C source file in the preprocessed output.

With `--preprocess=+includes` the compiler will generate a list of all included source files. The preprocessor output is discarded.

With `--preprocess=+list` the compiler will generate a list of all macro definitions. The preprocessor output is discarded.

With **--preprocess=+make** the compiler will generate dependency lines that can be used in a Makefile. The information is written to a file with extension `.d`. The preprocessor output is discarded. The default target name is the basename of the input file, with the extension `.o`. With the option **--make-target** you can specify a target name which overrules the default target name.

With **--preprocess=+noline** you tell the preprocessor to strip the `#line` source position information (lines starting with `#line`). These lines are normally processed by the assembler and not needed in the preprocessed output. When you leave these lines out, the output is easier to read.

Example

```
ccmcs --preprocess=+comments,-make,-noline --no-preprocessing-only test.c
```

The compiler preprocesses the file `test.c` and sends the output to the file `test.pre`. Comments are included but no dependencies are generated and the line source position information is not stripped from the output file. Next, the control program calls the compiler, assembler and linker to create the final object file `test.elf`

Related information

Control program option **--dep-file** (Generate dependencies in a file)

Control program option **--make-target** (Specify target name for **-Em** output)

Control program option: `--processors`

Menu entry

1. From the **Window** menu, select **Preferences**.

The Preferences dialog appears.

2. Select **TASKING » MCS**.
3. Click the **Add** button to add additional processor definition files.

Command line syntax

`--processors=file`

Description

With this option you can specify an additional XML file with processor definitions.

The standard list of supported processors is defined in the file `processors.xml`. This file defines for each processor its full name (for example, TC39xB), its ID, the base CPU name (for example, tc39xb) and the core settings (for example, mcs).

The control program reads the specified *file* after the file `processors.xml` in the product's `etc` directory. Additional XML files can override processor definitions made in XML files that are read before.

Multiple `--processors` options are allowed.

Eclipse generates a `--processors` option in the makefiles for each specified XML file.

Example

Specify an additional processor definition file (suppose `processors-new.xml` contains a new processor MCSNEW):

```
ccmcs --processors=processors-new.xml --cpu=MCSNEW test.c
```

Related information

Control program option `--cpu` (Select processor)

Control program option: `--signed-bitfields`

Menu entry

1. Select **C Compiler » Language**.
2. Enable the option **Treat 'int' bit-fields as signed**.

Command line syntax

`--signed-bitfields`

Description

For bit-fields it depends on the implementation whether a plain `int` is treated as `signed int` or `unsigned int`. By default an `int` bit-field is treated as `unsigned int`. This offers the best performance. With this option you tell the compiler to treat `int` bit-fields as `signed int`. In this case, you can still add the keyword `unsigned` to treat a particular `int` bit-field as `unsigned`.

Related information

C compiler option `--signed-bitfields`

Section 1.1, *Data Types*

Control program option: **--undefine (-U)**

Menu entry

1. Select **C Compiler » Preprocessing**

The Defined symbols box shows the symbols that are currently defined.

2. To remove a defined symbol, select the symbol in the **Defined symbols** box and click on the **Delete** button.

Command line syntax

--undefine=*macro_name*

-U*macro_name*

Description

With this option you can undefine an earlier defined macro as with `#undef`. This option is for example useful to undefine predefined macros.

The following predefined ISO C standard macros cannot be undefined:

<code>__FILE__</code>	current source filename
<code>__LINE__</code>	current source line number (int type)
<code>__TIME__</code>	hh:mm:ss
<code>__DATE__</code>	Mmm dd yyyy
<code>__STDC__</code>	level of ANSI standard

The control program passes the option **--undefine (-U)** to the compiler.

Example

To undefine the predefined macro `__TASKING__`:

```
ccmcs --undefine=__TASKING__ test.c
```

Related information

Control program option **--define** (Define preprocessor macro)

Section 1.8, *Predefined Preprocessor Macros*

Control program option: **--verbose (-v)**

Menu entry

1. Select **Global Options**.
2. Enable the option **Verbose mode of control program**.

Command line syntax

--verbose

-v

Description

With this option you put the control program in verbose mode. The control program performs its tasks while it prints the steps it performs to `stdout`.

Related information

Control program option **--dry-run** (Verbose output and suppress execution)

Control program option: --version (-V)

Menu entry

-

Command line syntax

`--version`

`-V`

Description

Display version information. The control program ignores all other options or input files.

Related information

-

Control program option: `--warnings-as-errors`

Menu entry

1. Select **Global Options**.
2. Enable the option **Treat warnings as errors**.

Command line syntax

```
--warnings-as-errors [=number [-number] , ... ]
```

Description

If one of the tools encounters an error, it stops processing the file(s). With this option you tell the tools to treat warnings as errors or treat specific control program warning messages as errors:

- If you specify this option but without numbers, all warnings are treated as errors.
- If you specify this option with a number or a range, only the specified control program warnings are treated as an error. You can specify the option `--warnings-as-errors=number` multiple times.

Use one of the `--pass-tool` options to pass this option directly to a tool when a specific warning for that tool must be treated as an error. For example, use `--pass-c--warnings-as-errors=number` to treat a specific C compiler warning as an error.

Related information

Control program option `--no-warnings` (Suppress some or all warnings)

Control program option `--pass` (Pass option to tool)

8.5. Parallel Make Utility Options

When you build a project in Eclipse, Eclipse generates a makefile and uses the make utility **amk** to build all your files. However, you can also use the make utility directly from the command line to build your project.

The invocation syntax is:

```
amk [option...] [target...] [macro=def]
```

This section describes all options for the parallel make utility.

For detailed information about the parallel make utility and using makefiles see [Section 6.2, Make Utility amk](#).

Parallel make utility option: --always-rebuild (-a)

Command line syntax

```
--always-rebuild
```

```
-a
```

Description

Normally the make utility rebuilds only those files that are out of date. With this option you tell the make utility to rebuild *all* files, without checking whether they are out of date.

Example

```
amk -a
```

Rebuilds all your files, regardless of whether they are out of date or not.

Related information

-

Parallel make utility option: --change-dir (-G)

Command line syntax

`--change-dir=path`

`-G path`

Description

Normally you must call the make utility from the directory where your makefile and other files are stored.

With the option **-G** you can call the make utility from within another directory. The *path* is the path to the directory where your makefile and other files are stored and can be absolute or relative to your current directory.

The macro `SUBDIR` is defined with the value of *path*.

Example

Suppose your makefile and other files are stored in the directory `..\myfiles`. You can call the make utility, for example, as follows:

```
amk -G ..\myfiles
```

Related information

-

Parallel make utility option: `--diag`

Command line syntax

```
--diag=[format:]{all | msg[-msg], ...}
```

You can set the following output formats:

html	HTML output.
rtf	Rich Text Format.
text	ASCII text.

Default format: text

Description

With this option you can ask for an extended description of error messages in the format you choose. The output is directed to stdout (normally your screen) and in the format you specify. You can specify the following formats: **html**, **rtf** or **text** (default). To create a file with the descriptions, you must redirect the output.

With the suboption **all**, the descriptions of all error messages are given. If you want the description of one or more selected error messages, you can specify the error message numbers, separated by commas, or you can specify a range.

Example

To display an explanation of message number 169, enter:

```
amk --diag=451
```

This results in the following message and explanation:

```
E451: make stopped
```

```
An error has occurred while executing one of the commands
of the target, and -k option is not specified.
```

To write an explanation of all errors and warnings in HTML format to file `amkerrors.html`, use redirection and enter:

```
amk --diag=html:all > amkerrors.html
```

Related information

-

Parallel make utility option: `--dry-run (-n)`

Command line syntax

`--dry-run`

`-n`

Description

With this option you tell the make utility to perform a dry run. The make utility shows what it would do but does not actually perform these tasks.

This option is for example useful to quickly inspect what would happen if you call the make utility.

Example

```
amk -n
```

The make utility does not perform any tasks but displays what it would do if called without the option `-n`.

Related information

[Parallel make utility option `-s`](#) (Do not print commands before execution)

Parallel make utility option: --help (-? / -h)

Command line syntax

```
--help[=item]
```

```
-h[item]
```

```
-?
```

You can specify the following arguments:

options o Show extended option descriptions

Description

Displays an overview of all command line options. When you specify the argument **options** you can list detailed option descriptions.

Example

The following invocations all display a list of the available command line options:

```
amk -?  
amk -h  
amk --help
```

To see a detailed description of the available options, enter:

```
amk --help=options
```

Related information

-

Parallel make utility option: --jobs (-j) / --jobs-limit (-J)

Menu

1. From the **Project** menu, select **Properties for**
The Properties dialog appears.
2. In the left pane, select **C/C++ Build**.
In the right pane the C/C++ Build page appears.
3. On the Behavior tab, select **Enable parallel build**.
4. You can specify the number of parallel jobs, or you can use an optimal number of jobs. In the last case, **amk** will fork as many jobs in parallel as cores are available.

Command line syntax

```
--jobs [=number]  
-j [number]  
  
--jobs-limit [=number]  
-J [number]
```

Description

When these options you can limit the number of parallel jobs. The default is 1. Zero means no limit. When you omit the *number*, **amk** uses the number of cores detected.

Option **-J** is the same as **-j**, except that the number of parallel jobs is limited by the number of cores detected.

Example

```
amk -j3
```

Limit the number of parallel jobs to 3.

Related information

-

Parallel make utility option: --keep-going (-k)

Command line syntax

`--keep-going`

`-k`

Description

When during the make process the make utility encounters an error, it stops rebuilding your files.

With the option `-k`, the make utility only stops building the target that produced the error. All other targets defined in the makefile are built.

Example

```
amk -k
```

If the make utility encounters an error, it stops building the current target but proceeds with the other targets that are defined in the makefile.

Related information

-

Parallel make utility option: `--list-targets (-l)`

Command line syntax

`--list-targets`

`-l`

Description

With this option, the make utility lists all "primary" targets that are out of date.

Example

```
amk -l  
list of targets
```

Related information

-

Parallel make utility option: --makefile (-f)

Command line syntax

```
--makefile=my_makefile
```

```
-f my_makefile
```

Description

By default the make utility uses the file `makefile` to build your files.

With this option you tell the make utility to use the specified file instead of the file `makefile`. Multiple `-f` options act as if all the makefiles were concatenated in a left-to-right order.

If you use `'-'` instead of a makefile name it means that the information is read from `stdin`.

Example

```
amk -f mymake
```

The make utility uses the file `mymake` to build your files.

Related information

-

Parallel make utility option: **--no-warnings (-w)**

Command line syntax

--no-warnings[=*number*, ...]

-w[*number*, ...]

Description

With this option you can suppresses all warning messages or specific warning messages.

On the command line this option works as follows:

- If you do not specify this option, all warnings are reported.
- If you specify this option but without numbers, all warnings are suppressed.
- If you specify this option with a number, only the specified warning is suppressed. You can specify the option **--no-warnings=number** multiple times.

Example

To suppress warnings 751 and 756, enter:

```
amk --no-warnings=751,756
```

Related information

Parallel make utility option **--warnings-as-errors** (Treat warnings as errors)

Parallel make utility option: **--silent (-s)**

Command line syntax

`--silent`

`-s`

Description

With this option you tell the make utility to perform its tasks without printing the commands it executes. Error messages are normally printed.

Example

```
amk -s
```

The make utility rebuilds your files but does not print the commands it executes during the make process.

Related information

[Parallel make utility option -n](#) (Perform a dry run)

Parallel make utility option: --version (-V)

Command line syntax

`--version`

`-V`

Description

Display version information. The make utility ignores all other options or input files.

Related information

-

Parallel make utility option: `--warnings-as-errors`

Command line syntax

```
--warnings-as-errors [=number, ...]
```

Description

If the make utility encounters an error, it stops. When you use this option without arguments, you tell the make utility to treat all warnings as errors. This means that the exit status of the make utility will be non-zero after one or more warnings. As a consequence, the make utility now also stops after encountering a warning.

You can also limit this option to specific warnings by specifying a comma-separated list of warning numbers.

Related information

Parallel make utility option `--no-warnings` (Suppress some or all warnings)

8.6. Archiver Options

The archiver and library maintainer **armcs** is a tool to build library files and it offers the possibility to replace, extract and remove modules from an existing library.

The invocation syntax is:

```
armcs key_option [sub_option...] library [object_file]
```

This section describes all options for the archiver. Some suboptions can only be used in combination with certain key options. They are described together. Suboptions that can always be used are described separately.

For detailed information about the archiver, see [Section 6.3, Archiver](#).

Short and long option names

Options can have both short and long names. Short option names always begin with a single minus (-) character, long option names always begin with two minus (--) characters. You can abbreviate long option names as long as it forms a unique name. You can mix short and long option names on the command line.

Overview of the options of the archiver utility

The following archiver options are available:

Description	Option	Sub-option
Main functions (key options)		
Replace or add an object module	-r	-a -b -c -n -u -v
Extract an object module from the library	-x	-o -v
Delete object module from library	-d	-v
Move object module to another position	-m	-a -b -v
Print a table of contents of the library	-t	-s0 -s1
Print object module to standard output	-p	
Sub-options		
Append or move new modules after existing module <i>name</i>	-a name	
Append or move new modules before existing module <i>name</i>	-b name	
Suppress the message that is displayed when a new library is created	-c	
Create a new library from scratch	-n	
Preserve last-modified date from the library	-o	
Print symbols in library modules	-s{0 1}	
Replace only newer modules	-u	
Verbose	-v	

Description	Option	Sub-option
Miscellaneous		
Display options	-?	
Display description of one or more diagnostic messages	--diag	
Display version header	-V	
Read options from <i>file</i>	-f file	
Suppress warnings above level <i>n</i>	-wn	

Archiver option: **--delete (-d)**

Command line syntax

`--delete` [`--verbose`]

`-d` [`-v`]

Description

Delete the specified object modules from a library. With the suboption **--verbose (-v)** the archiver shows which files are removed.

--verbose **-v** Verbose: the archiver shows which files are removed.

Example

```
armcs --delete mylib.a obj1.o obj2.o
```

The archiver deletes `obj1.o` and `obj2.o` from the library `mylib.a`.

```
armcs -d -v mylib.a obj1.o obj2.o
```

The archiver deletes `obj1.o` and `obj2.o` from the library `mylib.a` and displays which files are removed.

Related information

-

Archiver option: `--diag`

Command line syntax

```
--diag=[format:] {all | msg[-msg], ...}
```

You can set the following output formats:

html	HTML output.
rtf	Rich Text Format.
text	ASCII text.

Default format: text

Description

With this option you can ask for an extended description of error messages in the format you choose. The output is directed to stdout (normally your screen) and in the format you specify. The archiver does not perform any actions. You can specify the following formats: **html**, **rtf** or **text** (default). To create a file with the descriptions, you must redirect the output.

With the suboption **all**, the descriptions of all error messages are given. If you want the description of one or more selected error messages, you can specify the error message numbers, separated by commas, or you can specify a range.

Example

To display an explanation of message number 102, enter:

```
armcs --diag=102
```

This results in the following message and explanation:

```
F102: cannot create "<file>"
```

The output file or a temporary file could not be created. Check if you have sufficient disk space and if you have write permissions for the specified file.

To write an explanation of all errors and warnings in HTML format to file `arerrors.html`, use redirection and enter:

```
armcs --diag=html:all > arerrors.html
```

Related information

-

Archiver option: `--dump (-p)`

Command line syntax

`--dump`

`-p`

Description

Print the specified object module(s) in the library to standard output.

This option is only useful when you redirect or pipe the output to other files or tools that serve your own purposes. Normally you do not need this option.

Example

```
armcs --dump mylib.a obj1.o > file.o
```

The archiver prints the file `obj1.o` to standard output where it is redirected to the file `file.o`. The effect of this example is very similar to extracting a file from the library but in this case the 'extracted' file gets another name.

Related information

-

Archiver option: **--extract (-x)**

Command line syntax

```
--extract [--modtime] [--verbose]
```

```
-x [-o] [-v]
```

Description

Extract an existing module from the library.

--modtime	-o	Give the extracted object module the same date as the last-modified date that was recorded in the library. Without this suboption it receives the last-modified date of the moment it is extracted.
--verbose	-v	Verbose: the archiver shows which files are extracted.

Example

To extract the file `obj1.o` from the library `mylib.a`:

```
armcs --extract mylib.a obj1.o
```

If you do not specify an object module, all object modules are extracted:

```
armcs -x mylib.a
```

Related information

-

Archiver option: --help (-?)

Command line syntax

`--help[=item]`

`-?`

You can specify the following argument:

options	Show extended option descriptions
----------------	-----------------------------------

Description

Displays an overview of all command line options. When you specify the argument **options** you can list detailed option descriptions.

Example

The following invocations all display a list of the available command line options:

```
armcs -?  
armcs --help  
armcs
```

To see a detailed description of the available options, enter:

```
armcs --help=options
```

Related information

-

Archiver option: **--move (-m)**

Command line syntax

```
--move [-a posname] [-b posname]
```

```
-m [-a posname] [-b posname]
```

Description

Move the specified object modules to another position in the library.

The ordering of members in a library can make a difference in how programs are linked if a symbol is defined in more than one member.

By default, the specified members are moved to the end of the archive. Use the suboptions **-a** or **-b** to move them to a specified place instead.

--after=<i>posname</i>	-a	Move the specified object module(s) after the existing module <i>posname</i> .
--before=<i>posname</i>	-b	Move the specified object module(s) before the existing module <i>posname</i> .

Example

Suppose the library `mylib.a` contains the following objects (see option **--print**):

```
obj1.o
obj2.o
obj3.o
```

To move `obj1.o` to the end of `mylib.a`:

```
armcs --move mylib.a obj1.o
```

To move `obj3.o` just before `obj2.o`:

```
armcs -m -b obj3.o mylib.a obj2.o
```

The library `mylib.a` after these two invocations now looks like:

```
obj3.o
obj2.o
obj1.o
```

Related information

Archiver option **--print (-t)** (Print library contents)

Archiver option: **--option-file (-f)**

Command line syntax

--option-file=*file*

-f *file*

Description

Instead of typing all options on the command line, you can create an option file which contains all options and flags you want to specify. With this option you specify the option file to the archiver.

Use an option file when the command line would exceed the limits of the operating system, or just to store options and save typing.

You can specify the option **--option-file (-f)** multiple times.

If you use '-' instead of a filename it means that the options are read from `stdin`.

Format of an option file

- Multiple arguments on one line in the option file are allowed.
- To include whitespace in an argument, surround the argument with single or double quotes.
- If you want to use single quotes as part of the argument, surround the argument by double quotes and vice versa:

```
"This has a single quote ' embedded"
```

```
'This has a double quote " embedded'
```

```
'This has a double quote " and a single quote ''' embedded"
```

- When a text line reaches its length limit, use a `\` to continue the line. Whitespace between quotes is preserved.

```
"This is a continuation \  
line"
```

```
-> "This is a continuation line"
```

- It is possible to nest command line files up to 25 levels.

Example

Suppose the file `myoptions` contains the following lines:

```
-x mylib.a obj1.o  
-w5
```

Specify the option file to the archiver:

```
armcs --option-file=myoptions
```

This is equivalent to the following command line:

```
armcs -x mylib.a obj1.o -w5
```

Related information

-

Archiver option: --print (-t)

Command line syntax

```
--print [--symbols=0|1]
```

```
-t [-s0|-s1]
```

Description

Print a table of contents of the library to standard output. With the suboption **-s0** the archiver displays all symbols per object file.

--symbols=0	-s0	Displays per object the name of the object itself and all symbols in the object.
--symbols=1	-s1	Displays the symbols of all object files in the library in the form <i>library_name:object_name:symbol_name</i>

Example

```
armcs --print mylib.a
```

The archiver prints a list of all object modules in the library `mylib.a`:

```
armcs -t -s0 mylib.a
```

The archiver prints per object all symbols in the library.

Related information

-

Archiver option: --replace (-r)

Command line syntax

```
--replace [--after=posname] [--before=posname]
           [--create] [--new] [--newer-only] [--verbose]

-r [-a posname] [-b posname] [-c] [-n] [-u] [-v]
```

Description

You can use the option **--replace (-r)** for several purposes:

- Adding new objects to the library
- Replacing objects in the library with the same object of a newer date
- Creating a new library

The option **--replace (-r)** normally *adds* a new module to the library. However, if the library already contains a module with the specified name, the existing module is *replaced*. If you specify a library that does not exist, the archiver creates a new library with the specified name.

If you add a module to the library without specifying the suboption **-a** or **-b**, the specified module is added at the end of the archive. Use the suboptions **-a** or **-b** to insert them after/before a specified place instead.

--after=posname	-a posname	Insert the specified object module(s) after the existing module <i>posname</i> .
--before=posname	-b posname	Insert the specified object module(s) before the existing module <i>posname</i> .
--create	-c	Suppress the message that is displayed when a new library is created.
--new	-n	Create a new library from scratch. If the library already exists, it is overwritten.
--newer-only	-u	Insert the specified object module only if it is newer than the module in the library.
--verbose	-v	Verbose: the archiver shows which files are replaced.

The suboptions **-a** or **-b** have no effect when an object is added to the library.

Example

Suppose the library `mylib.a` contains the following object (see option **--print**):

```
obj1.o
```

To add `obj2.o` to the end of `mylib.a`:

```
armcs --replace mylib.a obj2.o
```

TASKING VX-toolset for MCS User Guide

To insert `obj3.o` just before `obj2.o`:

```
armcs -r -b obj2.o mylib.a obj3.o
```

The library `mylib.a` after these two invocations now looks like:

```
obj1.o  
obj3.o  
obj2.o
```

Creating a new library

To *create a new library file*, add an object file and specify a library that does not yet exist:

```
armcs --replace newlib.a obj1.o
```

The archiver creates the library `newlib.a` and adds the object `obj1.o` to it.

To *create a new library file and overwrite an existing library*, add an object file and specify an existing library with the supoption **--new (-n)**:

```
armcs -r -n mylib.a obj1.o
```

The archiver overwrites the library `mylib.a` and adds the object `obj1.o` to it. The new library `mylib.a` only contains `obj1.o`.

Related information

Archiver option **--print (-t)** (Print library contents)

Archiver option: --version (-V)

Command line syntax

`--version`

`-v`

Description

Display version information. The archiver ignores all other options or input files.

Related information

-

Archiver option: **--warning (-w)**

Command line syntax

`--warning=level`

`-wlevel`

Description

With this suboption you tell the archiver to suppress all warnings above the specified level. The level is a number between 0 - 9.

The level of a message is printed between parentheses after the warning number. If you do not use the `-w` option, the default warning level is 8.

Example

To suppress warnings above level 5:

```
armcs --extract --warning=5 mylib.a obj1.o
```

Related information

-

8.7. HLL Object Dumper Options

The high level language (HLL) dumper **hldumpmcs** is a program to dump information about an absolute object file (`.elf`).

Short and long option names

Options can have both short and long names. Short option names always begin with a single minus (-) character, long option names always begin with two minus (--) characters. You can abbreviate long option names as long as it forms a unique name. You can mix short and long option names on the command line.

Options can have flags or suboptions. To switch a flag 'on', use a lowercase letter or a *+longflag*. To switch a flag off, use an uppercase letter or a *-longflag*. Separate *longflags* with commas. The following two invocations are equivalent:

```
hldumpmcs -FdhMsy test.elf
hldumpmcs --dump-format=+dump,+hllsymbols,-modules,+sections,+symbols test.elf
```

When you do not specify an option, a default value may become active.

HLL object dumper option: **--adx-format (-A)**

Command line syntax

--adx-format [=flag], ...

-A [flag] ...

You can specify one of the following flags:

+/-force-elf-mode	e/E	Force the use of ELF symbols instead of the DWARF debug info
+/-reduced	r/R	Do not output tags CATEGORY, COMP-UNIT-NAME, COMP-UNIT-DIR and CALLED-SYMBOLS.

Default (no flags): **--adx-format=ER**

Description

With this option you dump the application data in the ADX address list format. The address list format is based on XML.

With **--adx-format=+force-elf-mode**, ELF symbols are used instead of the DWARF debug info, resulting in reduced info.

With **--adx-format=+reduced**, the tags CATEGORY, COMP-UNIT-NAME, COMP-UNIT-DIR and CALLED-SYMBOLS are not printed in the XML output.

Note that when you use this option all other output formatting options are ignored.

Example

```
hldumpmcs --adx-format hello.elf

<?xml version="1.0"?>
<!-- Using DWARF debug info -->
<ADDRESS-CALCULATOR version="1.0.4" spec="1.10">

ADX Specification - Address List Format for A2L Address Calculation - Compiler vendors, Version 1.10, 2015-04-27

HLL object dumper option: --blank-out (-b)

Command line syntax

```
--blank-out [=flag]
```

```
-b [flag]
```

You can specify the following format flags:

+/-labels **I/L** Black out hexadecimal address and labels.

Default: `--blank-out=L`

Description

With this option you can blank out addresses and optionally labels in all dump phases. Instead of the addresses and labels crosses (X's) are shown.

The **+labels** sub-option blanks out hexadecimal addresses and labels. With the **-labels** sub-option only hexadecimal addresses are blanked out. This is the default.

This option is useful when you want to compare the output, but want to ignore the addresses and labels.

Example

```
hldumpmcs -F2 hello.elf
```

```
----- Section dump -----
```

```

                                .sdecl  '.mcstext.hello.main', CODE AT 0x3f4

HLL object dumper option: --call-graph-elf-mode

Command line syntax

`--call-graph-elf-mode`

Description

With this option you can force the call graph to use the ELF symbols instead of the DWARF debug info, for example when dumping from an assembly function.

Related information

Section 6.4.2, *HLL Dump Output Format*

HLL object dumper option: --call-graph-root

Command line syntax

`--call-graph-root=function`

Description

With this option you can specify the address or function name where to start the call graph. By default, the call graph starts with `main()`.

Example

To start the call graph from `printf()` instead of `main()`, enter:

```
hldumpmcs --call-graph-root=printf -F3 hello.elf
```

The call graph looks something like this:

```
+-- 0x0000092c printf
  |
  +-- 0x00000474 _doprint
    |
    +-- 0x00000840 _io_putc
      |
      +-- 0x00000900 fputc
        |
        +-- 0x0000067c _flsbuf
          |
          +-- 0x00000820 _host_write
            |
            +-- 0x00000430 _dbg_trap
              |
              +-- 0x00000548 _fflush
                |
                +-- 0x00000820 _host_write *
                  |
                  +-- 0x000007e8 _host_lseek
                    |
                    +-- 0x00000430 _dbg_trap
                      |
                      +-- 0x00000820 _host_write *
                        |
                        +-- 0x00000840 _io_putc *
```

Section 6.4.2, *HLL Dump Output Format*

HLL object dumper option: `--class (-c)`

Command line syntax

```
--class[=class]
```

```
-c[class]
```

You can specify one of the following classes:

all	a	Dump contents of all sections.
code	c	Dump contents of code sections.
data	d	Dump contents of data sections.

Default: `--class=all`

Description

With this option you can restrict the output to code or data only. This option affects all parts of the output, except the module list. The effect is listed in the following table.

Output part	Effect of <code>--class</code>
Module list	Not restricted
Section list	Only lists sections of the specified class
Section dump	Only dumps the contents of the sections of the specified class
HLL symbol table	Only lists symbols of the specified class
Assembly level symbol table	Only lists symbols defined in sections of the specified class
Note sections	Not restricted

By default all sections are included.

Related information

[Section 6.4.2, HLL Dump Output Format](#)

HLL object dumper option: --copy-table

Command line syntax

`--copy-table`

Description

With this option the HLL object dumper attempts to translate the specified code address to the destination address of a copy table copy command during disassembly.

Related information

-

HLL object dumper option: `--diag`

Command line syntax

```
--diag=[format:]{all | msg[-msg], ...}
```

You can set the following output formats:

html	HTML output.
rtf	Rich Text Format.
text	ASCII text.

Default format: text

Description

With this option you can ask for an extended description of error messages in the format you choose. The output is directed to stdout (normally your screen) and in the format you specify. The HLL object dumper does not process any files. You can specify the following formats: **html**, **rtf** or **text** (default). To create a file with the descriptions, you must redirect the output.

With the suboption **all**, the descriptions of all error messages are given. If you want the description of one or more selected error messages, you can specify the error message numbers, separated by commas, or you can specify a range.

Example

To display an explanation of message number 101, enter:

```
hldumpmcs --diag=101
```

This results in the following message and explanation:

```
F101: cannot create "<file>"
```

```
The output file or a temporary file could not be created.
Check if you have sufficient disk space and if you have
write permissions for the specified file.
```

To write an explanation of all errors and warnings in HTML format to file `hldumperrors.html`, use redirection and enter:

```
hldumpmcs --diag=html:all > hldumperrors.html
```

HLL object dumper option: **--disassembly-intermix (-i)**

Command line syntax

--disassembly-intermix[=*flag*]

-i[*flag*]

You can specify the following format flags:

+/-single-line **s/S** Force the insert to be limited to the first preceding source line.

Default: **--disassembly-intermix=s**

Description

With this option the disassembly is intermixed with HLL source code. The source is searched for as described with option **--source-lookup-path**

The **+single-line** sub-option forces the insert to be limited to the first preceding source line. With the **-single-line** sub-option all source lines that belong to the address are prefixed. For example comments are thus also visible. This is the default.

Example

```
hldumpmcs --disassembly-intermix --source-lookup-path=c:\mylib\src hello.elf
```

Related information

HLL object dumper option **--source-lookup-path**

HLL object dumper option: --disassembly-without-encoding (-r)

Command line syntax

```
--disassembly-without-encoding
```

```
-r
```

Description

With this option the address and encoding are not part of the disassembly of a code section. This is useful when you only want the disassembly part.

Example

```
hldumpmcs -F2 hello.elf
```

```
----- Section dump -----
```

```

                                .sdecl '.mcstext.hello.main', CODE AT 0x3f4

HLL object dumper option: `--dump-format (-F)`

Command line syntax

`--dump-format [=flag, ...]`

`-F[flag]...`

You can specify the following format flags:

+/-callgraph	c/C	Dump the call graph of the application.
+/-dump	d/D	Dump the contents of the sections in the object file. Code sections can be disassembled, data sections are dumped.
+/-debug-control-flow	f/F	Dump the debug control flow section.
+/-hllsymbols	h/H	List the high level language symbols, with address, size and type.
+/-modules	m/M	Print a list of modules found in object file.
+/-note	n/N	Dump all ELF <code>.note</code> sections.
+/-sections	s/S	Print a list of sections with start address, length and type.
+/-symbols	y/Y	List the low level symbols, with address and length (if known).
	0	Alias for CDFHMNSY (nothing)
	1	Alias for CDFhMNSY (only HLL symbols)
	2	Alias for CdFHMNSY (only section contents)
	3	Alias for cdfhmnsy (everything)

Default: `--dump-format=CdFhmnsy`

Description

With this option you can control which parts of the dump output you want to see. By default, all parts are dumped, except for the call graph.

1. Module list
2. Section list
3. Call graph using the DWARF debug info
4. Section dump (disassembly)
5. HLL symbol table
6. Assembly level symbol table
7. Note sections
8. Debug control flow section

By default, all parts are dumped, except for parts 3 and 8.

You can limit the number of sections that will be dumped with the options **--sections** and **--section-types**.

Related information

[Section 6.4.2, *HLL Dump Output Format*](#)

HLL object dumper option: **--expand-symbols (-e)**

Command line syntax

```
--expand-symbols[=flag],...
```

```
-e[flag]...
```

You can specify one of the following flags:

+/-basic-types	b/B	Expand arrays with basic C types.
+/-fullpath	f/F	Include the full path to the field level.
+/-gap-info	g/G	Insert gap markers where data is not consecutive.
+/-nesting-indicator	n/N	Print nesting bars.

Default (no flags): `--expand-symbols=BFGN`

Description

With this option you specify that all struct, union and array symbols are expanded with their fields in the HLL symbol dump.

With `--expand-symbols=+basic-types`, HLL struct and union symbols are listed including all fields. Array members are expanded in one array member per line regardless of the HLL type. For the fields the types and names are indented with 2 spaces.

With `--expand-symbols=+fullpath`, all fields of structs and unions and all members of non-basic type arrays are expanded and prefixed with their parent's names.

With `--expand-symbols=+gap-info`, unused memory in complex data types (structures and unions) between data objects and between code objects is shown as `{gap}` parts. This option is useful to optimize data memory usage. This option only works if debug information is available in the ELF file.

With `--expand-symbols=+nesting-indicator`, vertical bars (|) are shown to make it easier to see the expanded structs, unions and arrays.

Example

```
hldumpmcs -F1 hello.elf
```

```
----- HLL symbol table -----
```

Address	Size	HLL Type	Name
00000020	24	struct	_dbg_request [dbg.c]
00000038	320	static char	stdin_buf[80] [_iob.c]

```
hldumpmcs -e -F1 hello.elf
```

```
----- HLL symbol table -----
```

```

Address      Size HLL Type      Name
00000020    24 struct      _dbg_request [dbg.c]
00000020     4  int        _errno

HLL object dumper option: --help (-?)

Command line syntax

`--help`

`-?`

Description

Displays an overview of all command line options.

Example

The following invocations all display a list of the available command line options:

```
hldumpmcs -?  
hldumpmcs --help  
hldumpmcs
```

Related information

-

HLL object dumper option: --hex (-x)

Command line syntax

--hex

-x

Description

With this option you can control the way data sections and code sections are dumped. By default, the contents of data sections are represented by directives. A new directive will be generated for each symbol. ELF labels in the section are used to determine the start of a directive. ROM sections are represented with `.word` directives, depending on the size of the data. RAM sections are represented with `.space` directives, with a size operand depending on the data size. This can be either the size specified in the ELF symbol, or the size up to the next label. Code sections are dumped as disassembly.

With option `--hex`, no directives will be generated for ROM data sections and no disassembly dump will be done for code sections. Instead ROM data sections and code sections are dumped as hexadecimal code with ASCII translation. RAM sections will be represented with only a start address and a size indicator.

Example

```
hldumpmcs -F2 --section=.mcsdata.hello.\$2\$str hello.elf
```

```
----- Section dump -----
```

```
.sdecl '.mcsdata.hello.$2$str',DATA AT 0x2d0
.sect  '.mcsdata.hello.$2$str'
.word 00000048,00000065,0000006c,0000006c; H...e...l...l...
.word 0000006f,0000002c,00000020,00000025; o...,... ..%...
.word 00000073,00000021,0000000a,00000000; s...!.....
```

```
hldumpmcs -F2 --section=.mcsdata.hello.\$2\$str --hex hello.elf
```

```
----- Section dump -----
```

```

                                section 7 (.mcsdata.hello.$2$str):
000002d0 48 00 00 00 65 00 00 00 6c 00 00 00 6c 00 00 00 H...e...l...l...
000002e0 6f 00 00 00 2c 00 00 00 20 00 00 00 25 00 00 00 o...,... ..%...
000002f0 73 00 00 00 21 00 00 00 0a 00 00 00 00 00 00 00 s...!.....
```

Related information

Section 6.4.2, *HLL Dump Output Format*

HLL object dumper option: `--option-file (-f)`

Command line syntax

```
--option-file=file,...
```

```
-f file,...
```

Description

This option is primarily intended for command line use. Instead of typing all options on the command line, you can create an option file which contains all options and flags you want to specify. With this option you specify the option file to the HLL object dumper.

Use an option file when the command line would exceed the limits of the operating system, or just to store options and save typing.

You can specify the option `--option-file` multiple times.

Format of an option file

- Multiple arguments on one line in the option file are allowed.
- To include whitespace in an argument, surround the argument with single or double quotes.
- If you want to use single quotes as part of the argument, surround the argument by double quotes and vice versa:

```
"This has a single quote ' embedded"
```

```
'This has a double quote " embedded'
```

```
'This has a double quote " and a single quote ''' embedded"
```

- When a text line reaches its length limit, use a `\` to continue the line. Whitespace between quotes is preserved.

```
"This is a continuation \  
line"
```

```
-> "This is a continuation line"
```

- It is possible to nest command line files up to 25 levels.

Example

Suppose the file `myoptions` contains the following lines:

```
--symbols=hll  
--class=code  
hello.elf
```

TASKING VX-toolset for MCS User Guide

Specify the option file to the HLL object dumper:

```
hldumpmcs --option-file=myoptions
```

This is equivalent to the following command line:

```
hldumpmcs --symbols=hll --class=code hello.elf
```

Related information

-

HLL object dumper option: `--output (-o)`

Command line syntax

```
--output=file
```

```
-o file
```

Description

By default, the HLL object dumper dumps the output on `stdout`. With this option you specify to dump the information in the specified file.

The default output format is text, but you can specify another output format with option `--output-type`.

Example

```
hldumpmcs --output=dump.txt hello.elf
```

The HLL object dumper dumps the output in file `dump.txt`.

Related information

HLL object dumper option `--output-type`

HLL object dumper option: `--output-type (-T)`

Command line syntax

`--output-type [=type]`

`-T [type]`

You can specify one of the following types:

text	t	Output human readable text.
xml	x	Output XML.

Default: `--output-type=text`

Description

With this option you can specify whether the output is formatted as plain text or as XML.

Related information

[HLL object dumper option `--output`](#)

HLL object dumper option: --sections (-s)

Command line syntax

`--sections=name,...`

`-sname,...`

Description

With this option you can restrict the output to the specified sections only. This option affects the following parts of the output:

Output part	Effect of --sections
Module list	Not restricted
Section list	Only lists the specified sections
Section dump	Only dumps the contents of the specified sections
HLL symbol table	Not restricted
Assembly level symbol table	Only lists symbols defined in the specified sections
Note sections	Not restricted

By default all sections are included.

Related information

[Section 6.4.2, HLL Dump Output Format](#)

HLL object dumper option: **--source-lookup-path (-L)**

Command line syntax

`--source-lookup-path=path`

`-Lpath`

Description

With this option you can specify an additional path where your source files are located. If you want to specify multiple paths, use the option **--source-lookup-path** for each separate path.

The order in which the HLL object dumper will search for source files when intermixed disassembly is used, is:

1. The path obtained from the HLL debug information.
2. The path that is specified with the option **--source-lookup-path**. If multiple paths are specified, the paths will be searched for in the order in which they are given on the command line.

Example

Suppose you call the HLL object dumper as follows:

```
hldumpmcs --disassembly-intermix --source-lookup-path=c:\mylib\src hello.elf
```

First the HLL object dumper looks in the directory found in the HLL debug information of file `hello.elf` for the location of the source file(s). If it does not find the file(s), it looks in the directory `c:\mylib\src`.

Related information

HLL object dumper option **--disassembly-intermix**

HLL object dumper option: `--symbols (-S)`

Command line syntax

`--symbols [=type]`

`-s [type]`

You can specify one of the following types:

asm	a	Display assembly symbols in code dump.
hll	h	Display HLL symbols in code dump.
none	n	Display plain addresses in code dump.

Default: `--symbols=asm`

Description

With this option you can control symbolic information in the disassembly and data dump. For data sections this only applies to symbols used as labels at the data addresses. Data within the data sections will never be replaced with symbols.

Only symbols that are available in the ELF or DWARF information are used. If you build an application without HLL debug information the `--symbols=hll` option will result in the same output as with `--symbols=none`. The same applies to the `--symbols=asm` option when all symbols are stripped from the ELF file.

Example

```
hldumpmcs -F2 hello.elf
```

```
----- Section dump -----

HLL object dumper option: --version (-V)

Command line syntax

`--version`

`-v`

Description

Display version information. The HLL object dumper ignores all other options or input files.

Related information

-

HLL object dumper option: `--xml-base-filename (-X)`

Command line syntax

`--xml-base-filename`

`-X`

Description

With this option the `<File name>` field in the XML output only contains the filename of the object file. By default, any path name, if present, is printed as well.

Example

```
hldumpmcs --output-type=xml --output=hello.xml ../hello.elf
```

The field `<File name=" ../hello.elf">` is used in `hello.xml`.

```
hldumpmcs --output-type=xml --output=hello.xml -X ../hello.elf
```

The field `<File name="hello.elf">` is used in `hello.xml`. The path is stripped from the filename.

Chapter 9. Influencing the Build Time

In general many settings have influence on the build time of a project. Any change in the tool settings of your project source will have more or less impact on the build time. The following sections describe several issues that can have significant influence on the build time.

9.1. Optimization Options

In general any optimization may require more work to be done by the compiler. But this does not mean that disabling all optimizations (level 0) gives the fastest compilation time. Disabling optimizations may result in more code being generated, resulting in more work for other parts of the compiler, like for example the register allocator.

9.2. Automatic Inlining

Automatic inlining is an optimization which can result in significant longer build time. The overall functions will get bigger, often making it possible to do more optimizations. But also often resulting in more registers to be in use in a function, giving the register allocation a tougher job.

9.3. Header Files

Many applications include all header files in each module, often by including them all within a single include file. Processing header files takes time. It is a good programming practice to only include the header files that are really required in a module, because:

- it is clear what interfaces are used by a module
- an incremental build after modifying a header file results in less modules required to be rebuild
- it reduces compile time

9.4. Parallel Build

The make utility **amk**, which is used by Eclipse, has a feature to build jobs in parallel. This means that multiple modules can be compiled in parallel. With today's multi-core processors this means that each core can be fully utilized. In practice even on single core machines the compile time decreases when using parallel jobs. On multi-core machines the build time even improves further when specifying more parallel jobs than the number of cores.

In Eclipse you can control the parallel build behavior:

1. From the **Project** menu, select **Properties for**

The Properties dialog appears.

2. In the left pane, select **C/C++ Build**.

In the right pane the C/C++ Build page appears.

3. On the Behavior tab, select **Enable parallel build**.
4. You can specify the number of parallel jobs, or you can use an optimal number of jobs. In the last case, **amk** will fork as many jobs in parallel as cores are available.

9.5. Section Concatenation

By default the linker does not merge sections with the same name into one section. With the [assembler option `--concatenate-sections`](#) the assembler uses the section attribute `concat`, instructing the linker to merge sections with the same name.

The advantage of section concatenation is faster locating, because there are less sections to locate.

The disadvantage of section concatenation is less efficient memory use, because of alignment gaps between (sequentially concatenated) sections.

Chapter 10. Libraries

This chapter contains an overview of all library functions that you can call in your C source. This includes all functions of the standard C library (ISO C99) and some functions of the floating-point library.

[Section 10.1, *Library Functions*](#), gives an overview of all library functions you can use, grouped per header file. A number of functions declared in `wchar.h` are parallel to functions in other header files. These are discussed together.

[Section 10.2, *C Library Reentrancy*](#), gives an overview of which functions are reentrant and which are not.

C library / floating-point library / run-time library

The following libraries are included in the MCS toolset. Both Eclipse and the control program `ccmcs` automatically select the appropriate libraries depending on the specified options.

Libraries	Description
libc[s].a	C libraries Optional letter: s = single precision floating-point (control program option <code>--fp-model=+float</code>)
libfp.a	Floating-point libraries (contains floating-point functions needed by the C compiler)
librt.a	Run-time library (contains other run-time functions needed by the C compiler)

The libraries are stored in the directory:

```
<installation path>\lib\mcs30\[be|le][\nmd] (MCS v3.0 libraries)  
<installation path>\lib\mcs31\[be|le][\nmd] (MCS v3.1 libraries)
```

The libraries are available in big-endian (be) or little-endian (le) variants. For MCS cores without multiply and/or divide support, the libraries are present in the `nmd` directory.

Sources for the libraries are present in the directories `lib\src`, `lib\src.*` in the form of an executable. If you run the executable it will extract the sources in the corresponding directory.

10.1. Library Functions

The tables in the sections below list all library functions, grouped per header file in which they are declared. Some functions are not completely implemented because their implementation depends on the context where your application will run. These functions are for example all I/O related functions. Where possible, these functions are implemented using file system simulation (FSS). This system can be used by the debugger to simulate an I/O environment which enables you to debug your application.

Wide character support

A number of wide character functions are available as C source code, but have not been compiled with the C library. To use complete wide character functionality, you must recompile the libraries with the macro `WCHAR_SUPPORT_ENABLED` and keep this macro also defined when compiling your own sources. See [C compiler option --define \(-D\)](#). The easiest way is to adapt the makefile for the library and change the CC line to:

```
CC = $(PRODDIR)\bin\cmcs -DWCHAR_SUPPORT_ENABLED
```

10.1.1. assert.h

`assert(expr)` Prints a diagnostic message if `NDEBUG` is not defined. (Implemented as macro)

For C11 only, the following macro is defined:

```
#define static_assert _Static_assert
```

10.1.2. complex.h

The complex number z is also written as $x+yi$ where x (the real part) and y (the imaginary part) are real numbers of types `float`, `double` or `long double`. The real and imaginary part can be stored in structs or in arrays. This implementation uses arrays because structs may have different alignments.

The header file `complex.h` also defines the following macros for backward compatibility:

```
complex    _Complex    /* C99 keyword */
imaginary  _Imaginary  /* C99 keyword */
```

Parallel sets of functions are defined for double, float and long double. They are respectively named *function*, *functionf*, *functionl*. All long type functions, though declared in `complex.h`, are implemented as the `double` type variant which nearly always meets the requirement in embedded applications.

This implementation uses the obvious implementation for complex multiplication; and a more sophisticated implementation for division and absolute value calculations which handles underflow, overflow and infinities with more care. The ISO C99 `#pragma CX_LIMITED_RANGE` therefore has no effect.

Trigonometric functions

<code>csin</code>	<code>csinf</code>	<code>csinl</code>	Returns the complex sine of z .
<code>ccos</code>	<code>ccosf</code>	<code>ccosl</code>	Returns the complex cosine of z .
<code>ctan</code>	<code>ctanf</code>	<code>ctanl</code>	Returns the complex tangent of z .
<code>casin</code>	<code>casinf</code>	<code>casinl</code>	Returns the complex arc sine $\sin^{-1}(z)$.
<code>cacos</code>	<code>cacosf</code>	<code>cacosl</code>	Returns the complex arc cosine $\cos^{-1}(z)$.
<code>catan</code>	<code>catanf</code>	<code>catanl</code>	Returns the complex arc tangent $\tan^{-1}(z)$.
<code>csinh</code>	<code>csinhf</code>	<code>csinhl</code>	Returns the complex hyperbolic sine of z .
<code>ccosh</code>	<code>ccoshf</code>	<code>ccoshl</code>	Returns the complex hyperbolic cosine of z .

<code>ctanh</code>	<code>ctanhf</code>	<code>ctanhl</code>	Returns the complex hyperbolic tangent of z .
<code>casinh</code>	<code>casinhf</code>	<code>casinhl</code>	Returns the complex arc hyperbolic sinus of z .
<code>cacosh</code>	<code>cacoshf</code>	<code>cacoshl</code>	Returns the complex arc hyperbolic cosine of z .
<code>catanh</code>	<code>catanhf</code>	<code>catanhl</code>	Returns the complex arc hyperbolic tangent of z .

Exponential and logarithmic functions

<code>cexp</code>	<code>cexpf</code>	<code>cexpl</code>	Returns the result of the complex exponential function e^z .
<code>clog</code>	<code>clogf</code>	<code>clogl</code>	Returns the complex natural logarithm.

Power and absolute-value functions

<code>cabs</code>	<code>cabsf</code>	<code>cabsl</code>	Returns the complex absolute value of z (also known as <i>norm</i> , <i>modulus</i> or <i>magnitude</i>).
<code>cpow</code>	<code>cpowf</code>	<code>cpowl</code>	Returns the complex value of x raised to the power y (x^y) where both x and y are complex numbers.
<code>csqrt</code>	<code>csqrtf</code>	<code>csqrtl</code>	Returns the complex square root of z .

Manipulation functions

<code>carg</code>	<code>cargf</code>	<code>cargl</code>	Returns the argument of z (also known as <i>phase angle</i>).
<code>cimag</code>	<code>cimagf</code>	<code>cimagl</code>	Returns the imaginary part of z as a real (respectively as a double, float, long double)
<code>conj</code>	<code>conjf</code>	<code>conjl</code>	Returns the complex conjugate value (the sign of its imaginary part is reversed).
<code>cproj</code>	<code>cprojf</code>	<code>cprojl</code>	Returns the value of the projection of z onto the Riemann sphere.
<code>creal</code>	<code>crealf</code>	<code>creall</code>	Returns the real part of z as a real (respectively as a double, float, long double)

10.1.3. ctype.h and wctype.h

The header file `ctype.h` declares the following functions which take a character c as an integer type argument. The header file `wctype.h` declares parallel wide character functions which take a character c of the `wchar_t` type as argument.

<code>ctype.h</code>	<code>wctype.h</code>	Description
<code>isalnum</code>	<code>iswalnum</code>	Returns a non-zero value when c is an alphabetic character or a number ([A-Z][a-z][0-9]).
<code>isalpha</code>	<code>iswalpha</code>	Returns a non-zero value when c is an alphabetic character ([A-Z][a-z]).
<code>isblank</code>	<code>iswblank</code>	Returns a non-zero value when c is a blank character (tab, space...)
<code>iscntrl</code>	<code>iswcntrl</code>	Returns a non-zero value when c is a control character.
<code>isdigit</code>	<code>iswdigit</code>	Returns a non-zero value when c is a numeric character ([0-9]).

ctype.h	wctype.h	Description
<code>isgraph</code>	<code>iswgraph</code>	Returns a non-zero value when <code>c</code> is printable, but not a space.
<code>islower</code>	<code>iswlower</code>	Returns a non-zero value when <code>c</code> is a lowercase character ([a-z]).
<code>isprint</code>	<code>iswprint</code>	Returns a non-zero value when <code>c</code> is printable, including spaces.
<code>ispunct</code>	<code>iswpunct</code>	Returns a non-zero value when <code>c</code> is a punctuation character (such as '!', ',', '!').
<code>isspace</code>	<code>iswspace</code>	Returns a non-zero value when <code>c</code> is a space type character (space, tab, vertical tab, formfeed, linefeed, carriage return).
<code>isupper</code>	<code>iswupper</code>	Returns a non-zero value when <code>c</code> is an uppercase character ([A-Z]).
<code>isxdigit</code>	<code>iswxdigit</code>	Returns a non-zero value when <code>c</code> is a hexadecimal digit ([0-9][A-F][a-f]).
<code>tolower</code>	<code>towlower</code>	Returns <code>c</code> converted to a lowercase character if it is an uppercase character, otherwise <code>c</code> is returned.
<code>toupper</code>	<code>towupper</code>	Returns <code>c</code> converted to an uppercase character if it is a lowercase character, otherwise <code>c</code> is returned.
<code>_tolower</code>	-	Converts <code>c</code> to a lowercase character, does not check if <code>c</code> really is an uppercase character. Implemented as macro. This macro function is not defined in ISO C99.
<code>_toupper</code>	-	Converts <code>c</code> to an uppercase character, does not check if <code>c</code> really is a lowercase character. Implemented as macro. This macro function is not defined in ISO C99.
<code>isascii</code>		Returns a non-zero value when <code>c</code> is in the range of 0 and 127. This function is not defined in ISO C99.
<code>toascii</code>		Converts <code>c</code> to an ASCII value (strip highest bit). This function is not defined in ISO C99.

10.1.4. dbg.h

The header file `dbg.h` contains the debugger call interface for file system simulation. It contains low level functions. This header file is not defined in ISO C99.

<code>_dbg_trap</code>	Low level function to trap debug events
<code>_argcv(const char *buf, size_t size)</code>	Low level function for command line argument passing

10.1.5. errno.h

`int errno` External variable that holds implementation defined error codes.

The following error codes are defined as macros in `errno.h`:

<code>EPERM</code>	1	Operation not permitted
<code>ENOENT</code>	2	No such file or directory
<code>EINTR</code>	3	Interrupted system call

EIO	4	I/O error
EBADF	5	Bad file number
EAGAIN	6	No more processes
ENOMEM	7	Not enough core
EACCES	8	Permission denied
EFAULT	9	Bad address
EEXIST	10	File exists
ENOTDIR	11	Not a directory
EISDIR	12	Is a directory
EINVAL	13	Invalid argument
ENFILE	14	File table overflow
EMFILE	15	Too many open files
ETXTBSY	16	Text file busy
ENOSPC	17	No space left on device
ESPIPE	18	Illegal seek
EROFS	19	Read-only file system
EPIPE	20	Broken pipe
ELOOP	21	Too many levels of symbolic links
ENAMETOOLONG	22	File name too long

Floating-point errors

EDOM	23	Argument too large
ERANGE	24	Result too large

Errors returned by printf/scanf

ERR_FORMAT	25	Illegal format string for printf/scanf
ERR_NOFLOAT	26	Floating-point not supported
ERR_NOLONG	27	Long not supported
ERR_NOPOINT	28	Pointers not supported

Encoding errors set by functions like fgetwc, getwc, mbrtowc, etc ...

EILSEQ	29	Invalid or incomplete multibyte or wide character
--------	----	---

Errors returned by RTOS

ECANCELED	30	Operation canceled
ENODEV	31	No such device

10.1.6. fcntl.h

The header file `fcntl.h` contains the function `open()`, which calls the low level function `_open()`, and definitions of flags used by the low level function `_open()`. This header file is not defined in ISO C99.

`open` Opens a file a file for reading or writing. Calls `_open`.
(FSS implementation)

10.1.7. fenv.h

Contains mechanisms to control the floating-point environment.

<code>fegetenv</code>	Stores the current floating-point environment.
<code>feholdexcept</code>	Saves the current floating-point environment and installs an environment that ignores all floating-point exceptions.
<code>fesetenv</code>	Restores a previously saved (<code>fegetenv</code> or <code>feholdexcept</code>) floating-point environment.
<code>feupdateenv</code>	Saves the currently raised floating-point exceptions, restores a previously saved floating-point environment and finally raises the saved exceptions.
<code>feclearexcept</code>	Clears the current exception status flags corresponding to the flags specified in the argument.
<code>fegetexceptflag</code>	Stores the current setting of the floating-point status flags.
<code>feraiseexcept</code>	Raises the exceptions represented in the argument. As a result, other exceptions may be raised as well.
<code>fesetexceptflag</code>	Sets the current floating-point status flags.
<code>fetestexcept</code>	Returns the bitwise-OR of the exception macros corresponding to the exception flags which are currently set <i>and</i> are specified in the argument.

For each supported exception, a macro is defined. The following exceptions are defined:

<code>FE_DIVBYZERO</code>	<code>FE_INEXACT</code>	<code>FE_INVALID</code>
<code>FE_OVERFLOW</code>	<code>FE_UNDERFLOW</code>	<code>FE_ALL_EXCEPT</code>

<code>fegetround</code>	Returns the current rounding direction, represented as one of the values of the rounding direction macros.
<code>fesetround</code>	Sets the current rounding directions.

For each supported rounding mode, a macro is defined. The following rounding mode macro is defined:

`FE_TONEAREST`

10.1.8. float.h

The header file `float.h` defines the characteristics of the real floating-point types `float`, `double` and `long double`.

`float.h` used to contain prototypes for the functions `copysign(f)`, `isinf(f)`, `isfinite(f)`, `isnan(f)` and `scalb(f)`. These functions have accordingly to the ISO C99 standard been moved to the header file `math.h`. See also [Section 10.1.15, `math.h` and `tgmath.h`](#).

The following functions are only available for ISO C90:

<code>copysignf(float f, float s)</code>	Copies the sign of the second argument <i>s</i> to the value of the first argument <i>f</i> and returns the result.
<code>copysign(double d, double s)</code>	Copies the sign of the second argument <i>s</i> to the value of the first argument <i>d</i> and returns the result.
<code>isinf(float f)</code>	Test the variable <i>f</i> on being an infinite (IEEE-754) value.
<code>isinf(double d);</code>	Test the variable <i>d</i> on being an infinite (IEEE-754) value.
<code>isfinite(float f)</code>	Test the variable <i>f</i> on being a finite (IEEE-754) value.
<code>isfinite(double d)</code>	Test the variable <i>d</i> on being a finite (IEEE-754) value.
<code>isnan(float f)</code>	Test the variable <i>f</i> on being NaN (Not a Number, IEEE-754) .
<code>isnan(double d)</code>	Test the variable <i>d</i> on being NaN (Not a Number, IEEE-754) .
<code>scalbf(float f, int p)</code>	Returns $f * 2^p$ for integral values without computing 2^p .
<code>scalb(double d, int p)</code>	Returns $d * 2^p$ for integral values without computing 2^p . (See also <code>scalbn</code> in Section 10.1.15 , math.h and tgmath.h)

10.1.9. inttypes.h and stdint.h

The header files `stdint.h` and `inttypes.h` provide additional declarations for integer types and have various characteristics. The `stdint.h` header file contains basic definitions of integer types of certain sizes, and corresponding sets of macros. This header file clearly refers to the corresponding sections in the ISO C99 standard.

The `inttypes.h` header file includes `stdint.h` and adds portable formatting and conversion functions. Below the conversion functions from `inttypes.h` are listed.

<code>imaxabs(intmax_t j)</code>	Returns the absolute value of <i>j</i>
<code>imaxdiv(intmax_t numer, intmax_t denom)</code>	Computes <code>numer/denom</code> and <code>numer % denom</code> . The result is stored in the <code>quot</code> and <code>rem</code> components of the <code>imaxdiv_t</code> structure type.
<code>strtoimax(const char * restrict nptr, char ** restrict endptr, int base)</code>	Convert string to maximum sized integer. (Compare <code>strtoll</code>)
<code>strtoumax(const char * restrict nptr, char ** restrict endptr, int base)</code>	Convert string to maximum sized unsigned integer. (Compare <code>strtoull</code>)
<code>wcstoimax(const wchar_t * restrict nptr, wchar_t ** restrict endptr, int base)</code>	Convert wide string to maximum sized integer. (Compare <code>wcstoll</code>)
<code>wcstoumax(const wchar_t * restrict nptr, wchar_t ** restrict endptr, int base)</code>	Convert wide string to maximum sized unsigned integer. (Compare <code>wcstoull</code>)

10.1.10. io.h

The header file `io.h` contains prototypes for low level I/O functions. This header file is not defined in ISO C99.

TASKING VX-toolset for MCS User Guide

<code>_close(<i>fd</i>)</code>	Used by the functions <code>close</code> and <code>fclose</code> . (<i>FSS implementation</i>)
<code>_lseek(<i>fd, offset, whence</i>)</code>	Used by all file positioning functions: <code>fgetpos</code> , <code>fseek</code> , <code>fsetpos</code> , <code>ftell</code> , <code>rewind</code> . (<i>FSS implementation</i>)
<code>_open(<i>fd, flags</i>)</code>	Used by the functions <code>fopen</code> and <code>freopen</code> . (<i>FSS implementation</i>)
<code>_read(<i>fd, *buff, cnt</i>)</code>	Reads a sequence of characters from a file. (<i>FSS implementation</i>)
<code>_unlink(*<i>name</i>)</code>	Used by the function <code>remove</code> . (<i>FSS implementation</i>)
<code>_write(<i>fd, *buffer, cnt</i>)</code>	Writes a sequence of characters to a file. (<i>FSS implementation</i>)

10.1.11. iso646.h

The header file `iso646.h` adds tokens that can be used instead of regular operator tokens.

```
#define and      &&
#define and_eq  &=
#define bitand  &
#define bitor   |
#define compl   ~
#define not     !
#define not_eq  !=
#define or      ||
#define or_eq   |=
#define xor     ^
#define xor_eq  ^=
```

10.1.12. limits.h

Contains the sizes of integral types, defined as macros.

10.1.13. locale.h

To keep C code reasonable portable across different languages and cultures, a number of facilities are provided in the header file `locale.h`.

```
char *setlocale( int category, const char *locale )
```

The function above changes locale-specific features of the run-time library as specified by the category to change and the name of the locale.

The following categories are defined and can be used as input for this function:

<code>LC_ALL</code>	<code>0</code>	<code>LC_NUMERIC</code>	<code>3</code>
<code>LC_COLLATE</code>	<code>1</code>	<code>LC_TIME</code>	<code>4</code>
<code>LC_CTYPE</code>	<code>2</code>	<code>LC_MONETARY</code>	<code>5</code>

```
struct lconv *localeconv( void )
```

Returns a pointer to type `struct lconv` with values appropriate for the formatting of numeric quantities according to the rules of the current locale. The `struct lconv` in this header file is conforming the ISO standard.

10.1.14. malloc.h

The header file `malloc.h` contains prototypes for memory allocation functions. This include file is not defined in ISO C99, it is included for backwards compatibility with ISO C90. For ISO C99, the memory allocation functions are part of `stdlib.h`. See [Section 10.1.24, `stdlib.h` and `wchar.h`](#).

<code>malloc(size)</code>	Allocates space for an object with size <i>size</i> . The allocated space is not initialized. Returns a pointer to the allocated space.
<code>aligned_alloc(alignment, size)</code>	(C11 only) Allocates space for an object whose alignment is specified by <i>alignment</i> and with size <i>size</i> . The allocated space is not initialized. Returns a pointer to the allocated space.
<code>calloc(nobj, size)</code>	Allocates space for <i>n</i> objects with size <i>size</i> . The allocated space is initialized with zeros. Returns a pointer to the allocated space.
<code>free(*ptr)</code>	Deallocates the memory space pointed to by <i>ptr</i> which should be a pointer earlier returned by the <code>malloc</code> or <code>calloc</code> function.
<code>realloc(*ptr, size)</code>	Deallocates the old object pointed to by <i>ptr</i> and returns a pointer to a new object with size <i>size</i> , while preserving its contents. If the new size is smaller than the old size, some contents at the end of the old region will be discarded. If the new size is larger than the old size, all of the old contents are preserved and any bytes in the new object beyond the size of the old object will have indeterminate values.

10.1.15. math.h and tgmth.h

The header file `math.h` contains the prototypes for many mathematical functions. Before ISO C99, all functions were computed using the `double` type (the `float` was automatically converted to `double`, prior to calculation). In this ISO C99 version, parallel sets of functions are defined for `double`, `float` and `long double`. They are respectively named *function*, *functionf*, *functionl*. All `long` type functions, though declared in `math.h`, are implemented as the `double` type variant which nearly always meets the requirement in embedded applications.

The header file `tgmth.h` contains parallel type generic math macros whose expansion depends on the used type. `tgmth.h` includes `math.h` and the effect of expansion is that the correct `math.h` functions are called. The type generic macro, if available, is listed in the second column of the tables below.

Trigonometric and hyperbolic functions

<code>math.h</code>	<code>tgmth.h</code>	Description
<code>sin</code> <code>sinf</code> <code>sinl</code>	<code>sin</code>	Returns the sine of <i>x</i> .

math.h			tgmath.h	Description
cos	cosf	cosl	cos	Returns the cosine of x .
tan	tanf	tanl	tan	Returns the tangent of x .
asin	asinf	asinl	asin	Returns the arc sine $\sin^{-1}(x)$ of x .
acos	acosf	acosl	acos	Returns the arc cosine $\cos^{-1}(x)$ of x .
atan	atanf	atanl	atan	Returns the arc tangent $\tan^{-1}(x)$ of x .
atan2	atan2f	atan2l	atan2	Returns the result of: $\tan^{-1}(y/x)$.
sinh	sinhf	sinhl	sinh	Returns the hyperbolic sine of x .
cosh	coshf	coshl	cosh	Returns the hyperbolic cosine of x .
tanh	tanhf	tanh1	tanh	Returns the hyperbolic tangent of x .
asinh	asinhf	asinh1	asinh	Returns the arc hyperbolic sine of x .
acosh	acoshf	acosh1	acosh	Returns the non-negative arc hyperbolic cosine of x .
atanh	atanhf	atanhl	atanh	Returns the arc hyperbolic tangent of x .

Exponential and logarithmic functions

All of these functions are new in ISO C99, except for `exp`, `log` and `log10`.

math.h			tgmath.h	Description
exp	expf	expl	exp	Returns the result of the exponential function e^x .
exp2	exp2f	exp2l	exp2	Returns the result of the exponential function 2^x .
expm1	expm1f	expm1l	expm1	Returns the result of the exponential function $e^x - 1$.
log	logf	logl	log	Returns the natural logarithm $\ln(x)$, $x > 0$.
log10	log10f	log10l	log10	Returns the base-10 logarithm of x , $x > 0$.
log1p	log1pf	log1pl	log1p	Returns the base-e logarithm of $(1+x)$. $x < -1$.
log2	log2f	log2l	log2	Returns the base-2 logarithm of x . $x > 0$.
ilogb	ilogbf	ilogbl	ilogb	Returns the signed exponent of x as an integer. $x > 0$.
logb	logbf	logbl	logb	Returns the exponent of x as a signed integer in value in floating-point notation. $x > 0$.

frexp, ldexp, modf, scalbn, scalbln

math.h			tgmath.h	Description
frexp	frexpf	frexpl	frexp	Splits a float x into fraction f and exponent n , so that: $f = 0.0$ or $0.5 \leq f \leq 1.0$ and $f \cdot 2^n = x$. Returns f , stores n .
ldexp	ldexpf	ldexpl	ldexp	Inverse of <code>frexp</code> . Returns the result of $x \cdot 2^n$. (x and n are both arguments).
modf	modff	modfl	-	Splits a float x into fraction f and integer n , so that: $ f < 1.0$ and $f + n = x$. Returns f , stores n .

math.h		tgmath.h		Description
scalbn	scalbnf	scalbnl	scalbn	Computes the result of $x * FLT_RADIX^n$. efficiently, not normally by computing FLT_RADIX^n explicitly.
scalbln	scalblnf	scalblnl	scalbln	Same as <code>scalbn</code> but with argument <code>n</code> as long int.

Rounding functions

math.h		tgmath.h		Description
ceil	ceilf	ceill	ceil	Returns the smallest integer not less than <code>x</code> , as a double.
floor	floorf	floorl	floor	Returns the largest integer not greater than <code>x</code> , as a double.
rint	rintf	rintl	rint	Returns the rounded integer value as an <code>int</code> according to the current rounding direction. See <code>fenv.h</code> .
lrint	lrintf	lrintl	lrint	Returns the rounded integer value as a long int according to the current rounding direction. See <code>fenv.h</code> .
llrint	llrintf	llrintl	llrint	Returns the rounded integer value as a long long int according to the current rounding direction. See <code>fenv.h</code> .
nearbyint	nearbyintf	nearbyintl	nearbyint	Returns the rounded integer value as a floating-point according to the current rounding direction. See <code>fenv.h</code> .
round	roundf	roundl	round	Returns the nearest integer value of <code>x</code> as int.
lround	lroundf	lroundl	lround	Returns the nearest integer value of <code>x</code> as long int.
llround	llroundf	llroundl	llround	Returns the nearest integer value of <code>x</code> as long long int.
trunc	truncf	truncl	trunc	Returns the truncated integer value <code>x</code> .

Remainder after division

math.h		tgmath.h		Description
fmod	fmodf	fmodl	fmod	Returns the remainder <code>r</code> of $x - ny$. <code>n</code> is chosen as <code>trunc(x/y)</code> . <code>r</code> has the same sign as <code>x</code> .
remainder	remainderf	remainderl	remainder	Returns the remainder <code>r</code> of $x - ny$. <code>n</code> is chosen as <code>trunc(x/y)</code> . <code>r</code> may not have the same sign as <code>x</code> .
remquo	remquof	remquol	remquo	Same as <code>remainder</code> . In addition, the argument <code>*quo</code> is given a specific value (see ISO).

Power and absolute-value functions

math.h		tgmath.h		Description
cbrt	cbrtf	cbrtl	cbrt	Returns the real cube root of <code>x</code> ($=x^{1/3}$).
fabs	fabsf	fabsl	fabs	Returns the absolute value of <code>x</code> ($ x $). (<code>abs</code> , <code>labs</code> , <code>llabs</code> , <code>div</code> , <code>ldiv</code> , <code>lldiv</code> are defined in <code>stdlib.h</code>)
fma	fmaf	fmal	fma	Floating-point multiply add. Returns $x * y + z$.
hypot	hypotf	hypotl	hypot	Returns the square root of $x^2 + y^2$.

math.h		tgmath.h		Description
pow	powf	powl	power	Returns x raised to the power y (x^y). ¹
sqrt	sqrtf	sqrtl	sqrt	Returns the non-negative square root of x . $x \geq 0$.

¹With compiler option `--fp-model=fastlib` more precise versions of `pow`, `powf` and `powl` are used when the arguments have no fractional part. The macro `__PRECISE_LIB_FP__` is defined. By default, less precise versions are used.

Manipulation functions: copysign, nan, nextafter, nexttoward

math.h		tgmath.h		Description
copysign	copysignf	copysignll	copysign	Returns the value of x with the sign of y .
nan	nanf	nanl	-	Returns a quiet NaN, if available, with content indicated through <code>tagp</code> .
nextafter	nextafterf	nextafterl	nextafter	Returns the next representable value in the specified format after x in the direction of y . Returns y if $x=y$.
nexttoward	nexttowardf	nexttowardl	nexttoward	Same as <code>nextafter</code> , except that the second argument in all three variants is of type long double. Returns y if $x=y$.

Positive difference, maximum, minimum

math.h		tgmath.h		Description
fdim	fdimf	fdiml	fdim	Returns the positive difference between: $ x-y $.
fmax	fmaxf	fmaxl	fmax	Returns the maximum value of their arguments.
fmin	fminf	fminl	fmin	Returns the minimum value of their arguments.

Error and gamma

math.h		tgmath.h		Description
erf	erff	erfl	erf	Computes the error function of x .
erfc	erfcf	erfcl	erc	Computes the complementary error function of x .
lgamma	lgammaf	lgammal	lgamma	Computes the $*\log_e \Gamma(x) $
tgamma	tgammaf	tgammal	tgamma	Computes $\Gamma(x)$

Comparison macros

The next are implemented as macros. For any ordered pair of numeric values exactly one of the relationships - *less*, *greater*, and *equal* - is true. These macros are type generic and therefore do not have a parallel function in `tgmath.h`. All arguments must be expressions of real-floating type.

math.h	tgmath.h	Description
isgreater	-	Returns the value of $(x) > (y)$

math.h	tgmath.h	Description
isgreaterequal	-	Returns the value of $(x) \geq (y)$
isless	-	Returns the value of $(x) < (y)$
islessequal	-	Returns the value of $(x) \leq (y)$
islessgreater	-	Returns the value of $(x) < (y) \ \ (x) > (y)$
isunordered	-	Returns 1 if its arguments are unordered, 0 otherwise.

Classification macros

The next are implemented as macros. These macros are type generic and therefore do not have a parallel function in `tgmath.h`. All arguments must be expressions of real-floating type.

math.h	tgmath.h	Description
fpclassify	-	Returns the class of its argument: FP_INFINITE, FP_NAN, FP_NORMAL, FP_SUBNORMAL or FP_ZERO
isfinite	-	Returns a nonzero value if and only if its argument has a finite value
isinf	-	Returns a nonzero value if and only if its argument has an infinite value
isnan	-	Returns a nonzero value if and only if its argument has NaN value.
isnormal	-	Returns a nonzero value if an only if its argument has a normal value.
signbit	-	Returns a nonzero value if and only if its argument value is negative.

10.1.16. setjmp.h

The `setjmp` and `longjmp` in this header file implement a primitive form of non-local jumps, which may be used to handle exceptional situations. This facility is traditionally considered more portable than `signal.h`

```
int setjmp( jmp_buf env)    Records its caller's environment in env and returns 0.
void longjmp( jmp_buf env, int status)    Restores the environment previously saved with a call to setjmp().
```

10.1.17. signal.h

Signals are possible asynchronous events that may require special processing. Each signal is named by a number. The following signals are defined:

```
SIGINT    1    Receipt of an interactive attention signal
SIGILL    2    Detection of an invalid function message
```

TASKING VX-toolset for MCS User Guide

SIGFPE	3	An erroneous arithmetic operation (for example, zero divide, overflow)
SIGSEGV	4	An invalid access to storage
SIGTERM	5	A termination request sent to the program
SIGABRT	6	Abnormal termination, such as is initiated by the <code>abort</code> function

The next function sends the signal *sig* to the program:

```
int raise(int sig)
```

The next function determines how subsequent signals will be handled:

```
signalfunction *signal (int, signalfunction *);
```

The first argument specifies the signal, the second argument points to the signal-handler function or has one of the following values:

SIG_DFL	Default behavior is used
SIG_IGN	The signal is ignored

The function returns the previous value of `signalfunction` for the specific signal, or `SIG_ERR` if an error occurs.

10.1.18. stdalign.h

This C11 header file contains the following macro definitions about alignment:

```
#define alignas _Alignas  
#define __alignas_is_defined 1  
  
#define alignof _Alignof  
#define __alignof_is_defined 1
```

10.1.19. stdarg.h

The facilities in this header file gives you a portable way to access variable arguments lists, such as needed for `fprintf` and `vfprintf`. `va_copy` is new in ISO C99. This header file contains the following macros:

<code>va_arg(va_list ap, type)</code>	Returns the value of the next argument in the variable argument list. Its return type has the type of the given argument <code>type</code> . A next call to this macro will return the value of the next argument.
<code>va_copy(va_list dest, va_list src)</code>	This macro duplicates the current state of <code>src</code> in <code>dest</code> , creating a second pointer into the argument list. After this call, <code>va_arg()</code> may be used on <code>src</code> and <code>dest</code> independently.
<code>va_end(va_list ap)</code>	This macro must be called after the arguments have been processed. It should be called before the function using the macro 'va_start' is terminated.

`va_start(va_list ap, lastarg)` This macro initializes `ap`. After this call, each call to `va_arg()` will return the value of the next argument. In our implementation, `va_list` cannot contain any bit type variables. Also the given argument `lastarg` must be the last non-bit type argument in the list.

10.1.20. `stdbool.h`

This header file contains the following macro definitions. These names for boolean type and values are consistent with C++. You are allowed to `#undefine` or `redefine` the macros below.

```
#define bool          _Bool
#define true          1
#define false         0
#define __bool_true_false_are_defined 1
```

10.1.21. `stddef.h`

This header file defines the types for common use:

```
ptrdiff_t    Signed integer type of the result of subtracting two pointers.
size_t       Unsigned integral type of the result of the sizeof operator.
wchar_t      Integer type to represent character codes in large character sets.
```

Besides these types, the following macros are defined:

```
NULL         Expands to the null pointer constant (void *) 0 for C or 0 (zero) for C++.
offsetof(_type, _member) Expands to an integer constant expression with type size_t that is the offset in bytes of _member within structure type _type.
```

10.1.22. `stdint.h`

See [Section 10.1.9](#), [inttypes.h](#) and [stdint.h](#)

10.1.23. `stdio.h` and `wchar.h`

Types

The header file `stdio.h` contains functions for performing input and output. A number of functions also have a parallel wide character function or macro, defined in `wchar.h`. The header file `wchar.h` also includes `stdio.h`.

In the C language, many I/O facilities are based on the concept of streams. The `stdio.h` header file defines the data type `FILE` which holds the information about a stream. A `FILE` object is created with the function `fopen`. The pointer to this object is used as an argument in many of the in this header file. The `FILE` object can contain the following information:

- the current position within the stream

TASKING VX-toolset for MCS User Guide

- pointers to any associated buffers
- indications of for read/write errors
- end of file indication

The header file also defines type `fpos_t` as an unsigned `long`.

Macros

stdio.h	Description
<code>NULL</code>	Expands to the null pointer constant <code>(void *) 0</code> for C or 0 (zero) for C++.
<code>BUFSIZ</code>	Size of the buffer used by the <code>setbuf/setvbuf</code> function: 512
<code>EOF</code>	End of file indicator. Expands to <code>-1</code> .
<code>WEOF</code>	End of file indicator. Expands to <code>UINT_MAX</code> (defined in <code>limits.h</code>) NOTE: <code>WEOF</code> need not to be a negative number as long as its value does not correspond to a member of the wide character set. (Defined in <code>wchar.h</code>).
<code>FOPEN_MAX</code>	Number of files that can be opened simultaneously: 10
<code>FILENAME_MAX</code>	Maximum length of a filename: 100
<code>_IOFBF</code> <code>_IOLBF</code> <code>_IONBF</code>	Expand to an integer expression, suitable for use as argument to the <code>setvbuf</code> function.
<code>L_tmpnam</code>	Size of the string used to hold temporary file names: 8 (<code>tmpxxxxx</code>)
<code>TMP_MAX</code>	Maximum number of unique temporary filenames that can be generated: 0x8000
<code>SEEK_CUR</code> <code>SEEK_END</code> <code>SEEK_SET</code>	Expand to an integer expression, suitable for use as the third argument to the <code>fseek</code> function.
<code>stderr</code> <code>stdin</code> <code>stdout</code>	Expressions of type "pointer to FILE" that point to the FILE objects associated with standard error, input and output streams.

File access

stdio.h	Description
<code>fopen(name, mode)</code>	Opens a file for a given mode. Available modes are:

stdio.h	Description
"r"	read; open text file for reading
"w"	write; create text file for writing; if the file already exists, its contents is discarded
"a"	append; open existing text file or create new text file for writing at end of file
"r+"	open text file for update; reading and writing
"w+"	create text file for update; previous contents if any is discarded
"a+"	append; open or create text file for update, writes at end of file
	<i>(FSS implementation)</i>
<code>fclose(name)</code>	Flushes the data stream and closes the specified file that was previously opened with <code>fopen</code> . <i>(FSS implementation)</i>
<code>fflush(name)</code>	If stream is an output stream, any buffered but unwritten data is written. Else, the effect is undefined. <i>(FSS implementation)</i>
<code>freopen(name, mode, stream)</code>	Similar to <code>fopen</code> , but rather than generating a new value of type <code>FILE *</code> , the existing value is associated with a new stream. <i>(FSS implementation)</i>
<code>setbuf(stream, buffer)</code>	If <code>buffer</code> is <code>NULL</code> , buffering is turned off for the stream. Otherwise, <code>setbuf</code> is equivalent to: <code>(void) setvbuf(stream, buffer, _IOFBF, BUFSIZ)</code> .
<code>setvbuf(stream, buffer, mode, size)</code>	Controls buffering for the <code>stream</code> ; this function must be called before reading or writing. <code>Mode</code> can have the following values: <code>_IOFBF</code> causes full buffering <code>_IOLBF</code> causes line buffering of text files <code>_IONBF</code> causes no buffering. If <code>buffer</code> is not <code>NULL</code> , it will be used as a buffer; otherwise a buffer will be allocated. <code>size</code> determines the buffer size.

Formatted input/output

The `format` string of `printf` related functions can contain plain text mixed with conversion specifiers. Each conversion specifier should be preceded by a '%' character. The conversion specifier should be built in order:

- Flags (in any order):

- specifies left adjustment of the converted argument.

- + a number is always preceded with a sign character.
+ has higher precedence than `space`.

`space` a negative number is preceded with a sign, positive numbers with a space.

- 0 specifies padding to the field width with zeros (only for numbers).

- # specifies an alternate output form. For `o`, the first digit will be zero. For `x` or `X`, "0x" and "0X" will be prefixed to the number. For `e`, `E`, `f`, `g`, `G`, the output always contains a decimal point, trailing zeros are not removed.

TASKING VX-toolset for MCS User Guide

- A number specifying a minimum field width. The converted argument is printed in a field with at least the length specified here. If the converted argument has fewer characters than specified, it will be padded at the left side (or at the right when the flag '-' was specified) with spaces. Padding to numeric fields will be done with zeros when the flag '0' is also specified (only when padding left). Instead of a numeric value, also '*' may be specified, the value is then taken from the next argument, which is assumed to be of type `int`.
- A period. This separates the minimum field width from the precision.
- A number specifying the maximum length of a string to be printed. Or the number of digits printed after the decimal point (only for floating-point conversions). Or the minimum number of digits to be printed for an integer conversion. Instead of a numeric value, also '*' may be specified, the value is then taken from the next argument, which is assumed to be of type `int`.
- A length modifier 'h', 'hh', 'l', 'll', 'L', 'j', 'z' or 't'. 'h' indicates that the argument is to be treated as a `short` or `unsigned short`. 'hh' indicates that the argument is to be treated as a `char` or `unsigned char`. 'l' should be used if the argument is a `long` integer, 'll' for a `long long`. 'L' indicates that the argument is a `long double`. 'j' indicates a pointer to `intmax_t` or `uintmax_t`, 'z' indicates a pointer to `size_t` and 't' indicates a pointer to `ptrdiff_t`.

Flags, length specifier, period, precision and length modifier are optional, the conversion character is not. The conversion character must be one of the following, if a character following '%' is not in the list, the behavior is undefined:

Character Printed as	
d, i	<code>int</code> , signed decimal
o	<code>int</code> , unsigned octal
x, X	<code>int</code> , unsigned hexadecimal in lowercase or uppercase respectively
u	<code>int</code> , unsigned decimal
c	<code>int</code> , single character (converted to unsigned char)
s	<code>char *</code> , the characters from the string are printed until a NULL character is found. When the given precision is met before, printing will also stop
f, F	<code>double</code>
e, E	<code>double</code>
g, G	<code>double</code>
a, A	<code>double</code>
n	<code>int *</code> , the number of characters written so far is written into the argument. This should be a pointer to an integer in default memory. No value is printed.
p	pointer
r, lr	<code>__fract</code> , <code>__lfract</code>
R, lR	<code>__accum</code> , <code>__laccum</code>
%	No argument is converted, a '%' is printed.

printf conversion characters

All arguments to the `scanf` related functions should be pointers to variables (in default memory) of the type which is specified in the format string.

The format string can contain :

- Blanks or tabs, which are skipped.
- Normal characters (not '%'), which should be matched exactly in the input stream.
- Conversion specifications, starting with a '%' character.

Conversion specifications should be built as follows (in order) :

- A '*', meaning that no assignment is done for this field.
- A number specifying the maximum field width.
- The conversion characters `d`, `i`, `n`, `o`, `u` and `x` may be preceded by 'h' if the argument is a pointer to `short` rather than `int`, or by 'hh' if the argument is a pointer to `char`, or by 'l' (letter ell) if the argument is a pointer to `long` or by 'll' for a pointer to `long long`, 'j' for a pointer to `intmax_t` or `uintmax_t`, 'z' for a pointer to `size_t` or 't' for a pointer to `ptrdiff_t`. The conversion characters `e`, `f`, and `g` may be preceded by 'l' if the argument is a pointer to `double` rather than `float`, and by 'L' for a pointer to a `long double`.
- A conversion specifier. '*', maximum field width and length modifier are optional, the conversion character is not. The conversion character must be one of the following, if a character following '%' is not in the list, the behavior is undefined.

Length specifier and length modifier are optional, the conversion character is not. The conversion character must be one of the following, if a character following '%' is not in the list, the behavior is undefined.

Character Scanned as

<code>d</code>	<code>int</code> , signed decimal.
<code>i</code>	<code>int</code> , the integer may be given octal (i.e. a leading 0 is entered) or hexadecimal (leading "0x" or "0X"), or just decimal.
<code>o</code>	<code>int</code> , unsigned octal.
<code>u</code>	<code>int</code> , unsigned decimal.
<code>x</code>	<code>int</code> , unsigned hexadecimal in lowercase or uppercase.
<code>c</code>	single character (converted to unsigned char).
<code>s</code>	<code>char *</code> , a string of non white space characters. The argument should point to an array of characters, large enough to hold the string and a terminating NULL character.
<code>f</code> , <code>F</code>	<code>float</code>
<code>e</code> , <code>E</code>	<code>float</code>
<code>g</code> , <code>G</code>	<code>float</code>
<code>a</code> , <code>A</code>	<code>float</code>
<code>n</code>	<code>int *</code> , the number of characters written so far is written into the argument. No scanning is done.
<code>p</code>	pointer; hexadecimal value which must be entered without 0x- prefix.

Character Scanned as	
r, lr	__fract, __lfract
R, IR	__accum, __laccum
[...]	Matches a string of input characters from the set between the brackets. A NULL character is added to terminate the string. Specifying [...] includes the ']' character in the set of scanning characters.
[^...]	Matches a string of input characters not in the set between the brackets. A NULL character is added to terminate the string. Specifying [^...] includes the ']' character in the set.
%	Literal '%', no assignment is done.

scanf conversion characters

stdio.h	wchar.h	Description
<code>fscanf(stream, format, ...)</code>	<code>fwscanf(stream, format, ...)</code>	Performs a formatted read from the given <i>stream</i> . Returns the number of items converted successfully. (FSS implementation)
<code>scanf(format, ...)</code>	<code>wscanf(format, ...)</code>	Performs a formatted read from <code>stdin</code> . Returns the number of items converted successfully. (FSS implementation)
<code>sscanf(*s, format, ...)</code>	<code>swscanf(*s, format, ...)</code>	Performs a formatted read from the string <i>s</i> . Returns the number of items converted successfully.
<code>vfscanf(stream, format, arg)</code>	<code>vwscanf(stream, format, arg)</code>	Same as <code>fscanf/fwscanf</code> , but extra arguments are given as variable argument list <i>arg</i> . (See Section 10.1.19, <i>stdarg.h</i>)
<code>vscanf(format, arg)</code>	<code>vwscanf(format, arg)</code>	Same as <code>sscanf/swscanf</code> , but extra arguments are given as variable argument list <i>arg</i> . (See Section 10.1.19, <i>stdarg.h</i>)
<code>vsscanf(*s, format, arg)</code>	<code>vswscanf(*s, format, arg)</code>	Same as <code>scanf/wscanf</code> , but extra arguments are given as variable argument list <i>arg</i> . (See Section 10.1.19, <i>stdarg.h</i>)
<code>fprintf(stream, format, ...)</code>	<code>fwprintf(stream, format, ...)</code>	Performs a formatted write to the given <i>stream</i> . Returns EOF/WEOF on error. (FSS implementation)
<code>printf(format, ...)</code>	<code>wprintf(format, ...)</code>	Performs a formatted write to the stream <code>stdout</code> . Returns EOF/WEOF on error. (FSS implementation)
<code>sprintf(*s, format, ...)</code>	-	Performs a formatted write to string <i>s</i> . Returns EOF/WEOF on error.
<code>snprintf(*s, n, format, ...)</code>	<code>swprintf(*s, n, format, ...)</code>	Same as <code>sprintf</code> , but <i>n</i> specifies the maximum number of characters (including the terminating null character) to be written.

stdio.h	wchar.h	Description
<code>vfprintf(<i>stream</i>, <i>format</i>, <i>arg</i>)</code>	<code>vfwprintf(<i>stream</i>, <i>format</i>, <i>arg</i>)</code>	Same as <code>fprintf/fwprintf</code> , but extra arguments are given as variable argument list <i>arg</i> . (See Section 10.1.19, <i>stdarg.h</i>) (FSS implementation)
<code>vprintf(<i>format</i>, <i>arg</i>)</code>	<code>vwprintf(<i>format</i>, <i>arg</i>)</code>	Same as <code>printf/wprintf</code> , but extra arguments are given as variable argument list <i>arg</i> . (See Section 10.1.19, <i>stdarg.h</i>) (FSS implementation)
<code>vsprintf(<i>*s</i>, <i>format</i>, <i>arg</i>)</code>	<code>vswprintf(<i>*s</i>, <i>format</i>, <i>arg</i>)</code>	Same as <code>sprintf/swprintf</code> , but extra arguments are given as variable argument list <i>arg</i> . (See Section 10.1.19, <i>stdarg.h</i>)

The C library functions `printf()`, `fprintf()`, `vfprintf()`, `vsprintf()`, ... call one single function, `_doprint()`, that deals with the format string and arguments. The same applies to all `scanf` type functions, which call the function `_doscan()`, and also for the `wprintf` and `wscanf` type functions which call `_dowprint()` and `_dowscan()` respectively. The C library contains three versions of these routines: `int`, `long` and `long long` versions. If you use floating-point the formatter function for floating-point `_doflt()` or `_dowflt()` is called. Depending on the formatting arguments you use, the correct routine is used from the library. Of course the larger the version of the routine the larger your produced code will be.

Note that when you call any of the `printf/scanf` routines indirectly, the arguments are not known and always the `long long` version with floating-point support is used from the library.

Example:

```
#include <stdio.h>

long L;

void main(void)
{
    printf( "This is a long: %ld\n", L );
}
```

The linker extracts the `long` version without floating-point support from the library.

See also the description of `#pragma weak` in [Section 1.7, *Pragmas to Control the Compiler*](#).

Character input/output

stdio.h	wchar.h	Description
<code>fgetc(<i>stream</i>)</code>	<code>fgetwc(<i>stream</i>)</code>	Reads one character from <i>stream</i> . Returns the read character, or EOF/WEOF on error. (FSS implementation)

stdio.h	wchar.h	Description
<code>getc(stream)</code>	<code>getwc(stream)</code>	Same as <code>fgetc/fgetwc</code> except that is implemented as a macro. (FSS implementation) NOTE: Currently #defined as <code>getchar()/getwchar()</code> because FILE I/O is not supported. Returns the read character, or EOF/WEOF on error.
<code>getchar(stdin)</code>	<code>getwchar(stdin)</code>	Reads one character from the <code>stdin</code> stream. Returns the character read or EOF/WEOF on error. Implemented as macro. (FSS implementation)
<code>fgets(*s, n, stream)</code>	<code>fgetws(*s, n, stream)</code>	Reads at most the next $n-1$ characters from the <code>stream</code> into array <code>s</code> until a newline is found. Returns <code>s</code> or NULL or EOF/WEOF on error. (FSS implementation)
<code>gets(*s)</code>	-	(C90/C99 only) Reads characters from the <code>stdin</code> stream into array <code>s</code> until end-of-file is encountered or a newline is found. The newline is replaced by a NULL character. Returns <code>s</code> or NULL on EOF. (FSS implementation)
<code>ungetc(c, stream)</code>	<code>ungetwc(c, stream)</code>	Pushes character <code>c</code> back onto the input <code>stream</code> . Returns EOF/WEOF on error.
<code>fputc(c, stream)</code>	<code>fputwc(c, stream)</code>	Put character <code>c</code> onto the given <code>stream</code> . Returns EOF/WEOF on error. (FSS implementation)
<code>putc(c, stream)</code>	<code>putwc(c, stream)</code>	Same as <code>fputc/fputwc</code> except that is implemented as a macro. (FSS implementation)
<code>putchar(c, stdout)</code>	<code>putwchar(c, stdout)</code>	Put character <code>c</code> onto the <code>stdout</code> stream. Returns EOF/WEOF on error. Implemented as macro. (FSS implementation)
<code>fputs(*s, stream)</code>	<code>fputws(*s, stream)</code>	Writes string <code>s</code> to the given <code>stream</code> . Returns EOF/WEOF on error. (FSS implementation)
<code>puts(*s)</code>	-	Writes string <code>s</code> to the <code>stdout</code> stream. Returns EOF/WEOF on error. (FSS implementation)

Direct input/output

stdio.h	Description
<code>fread(ptr, size, nobj, stream)</code>	Reads <code>nobj</code> members of <code>size</code> bytes from the given <code>stream</code> into the array pointed to by <code>ptr</code> . Returns the number of elements successfully read. (FSS implementation)
<code>fwrite(ptr, size, nobj, stream)</code>	Writes <code>nobj</code> members of <code>size</code> bytes from to the array pointed to by <code>ptr</code> to the given <code>stream</code> . Returns the number of elements successfully written. (FSS implementation)

Random access

stdio.h	Description
<code>fseek(<i>stream</i>, <i>offset</i>, <i>origin</i>)</code>	Sets the position indicator for <i>stream</i> . (FSS implementation)
<p>When repositioning a binary file, the new position <i>origin</i> is given by the following macros:</p> <pre> SEEK_SET 0 <i>offset</i> characters from the beginning of the file SEEK_CUR 1 <i>offset</i> characters from the current position in the file SEEK_END 2 <i>offset</i> characters from the end of the file </pre>	
<code>ftell(<i>stream</i>)</code>	Returns the current file position for <i>stream</i> , or -1L on error. (FSS implementation)
<code>rewind(<i>stream</i>)</code>	Sets the file position indicator for the <i>stream</i> to the beginning of the file. This function is equivalent to: <pre>(void) fseek(<i>stream</i>, 0L, SEEK_SET); clearerr(<i>stream</i>);</pre> (FSS implementation)
<code>fgetpos(<i>stream</i>, <i>pos</i>)</code>	Stores the current value of the file position indicator for <i>stream</i> in the object pointed to by <i>pos</i> . (FSS implementation)
<code>fsetpos(<i>stream</i>, <i>pos</i>)</code>	Positions <i>stream</i> at the position recorded by <code>fgetpos</code> in <i>*pos</i> . (FSS implementation)

Operations on files

stdio.h	Description
<code>remove(<i>file</i>)</code>	Removes the named file, so that a subsequent attempt to open it fails. Returns a non-zero value if not successful.
<code>rename(<i>old</i>, <i>new</i>)</code>	Changes the name of the file from old name to new name. Returns a non-zero value if not successful.
<code>tmpfile()</code>	Creates a temporary file of the mode "wb+" that will be automatically removed when closed or when the program terminates normally. Returns a <code>file</code> pointer.
<code>tmpnam(<i>buffer</i>)</code>	Creates new file names that do not conflict with other file names currently in use. The new file name is stored in a <i>buffer</i> which must have room for <code>L_tmpnam</code> characters. Returns a pointer to the temporary name. The file names are created in the current directory and all start with "tmp". At most <code>TMP_MAX</code> unique file names can be generated.

Error handling

stdio.h	Description
<code>clearerr(<i>stream</i>)</code>	Clears the end of file and error indicators for <i>stream</i> .
<code>ferror(<i>stream</i>)</code>	Returns a non-zero value if the error indicator for <i>stream</i> is set.
<code>feof(<i>stream</i>)</code>	Returns a non-zero value if the end of file indicator for <i>stream</i> is set.

stdio.h	Description
<code>perror(*s)</code>	Prints <code>s</code> and the error message belonging to the integer <code>errno</code> . (See Section 10.1.5, <code>errno.h</code>)

10.1.24. `stdlib.h` and `wchar.h`

The header file `stdlib.h` contains general utility functions which fall into the following categories (Some have parallel wide character, declared in `wchar.h`)

- Numeric conversions
- Random number generation
- Memory management
- Environment communication
- Searching and sorting
- Integer arithmetic
- Multibyte/wide character and string conversions.

Macros

`EXIT_SUCCESS` Predefined exit codes that can be used in the `exit` function.
0
`EXIT_FAILURE`
1

`RAND_MAX` Highest number that can be returned by the `rand/srand` function.
32767

`MB_CUR_MAX` 1 Maximum number of bytes in a multibyte character for the extended character set specified by the current locale (category `LC_CTYPE`, see [Section 10.1.13, `locale.h`](#)).

Numeric conversions

The following functions convert the initial portion of a string `*s` to a double, `int`, `long int` and `long long int` value respectively.

```
double        atof(*s)
int            atoi(*s)
long          atol(*s)
long long     atoll(*s)
```

The following functions convert the initial portion of the string `*s` to a float, double and long double value respectively. `*endp` will point to the first character not used by the conversion.

stdlib.h		wchar.h	
float	strtof(*s,**endp)	float	wcstof(*s,**endp)
double	strtod(*s,**endp)	double	wcstod(*s,**endp)
long double	strtold(*s,**endp)	long double	wcstold(*s,**endp)

The following functions convert the initial portion of the string *s* to a long, long long, unsigned long and unsigned long long respectively. Base specifies the radix. *endp* will point to the first character not used by the conversion.

stdlib.h		wchar.h	
long	strtol(*s,**endp,base)	long	wcstol(*s,**endp,base)
long long	strtoll(*s,**endp,base)	long long	wcstoll(*s,**endp,base)
unsigned long	strtoul(*s,**endp,base)	unsigned long	wcstoul(*s,**endp,base)
unsigned long long	strtoull(*s,**endp,base)	unsigned long long	wcstoull(*s,**endp,base)

Random number generation

`rand` Returns a pseudo random integer in the range 0 to `RAND_MAX`.
`srand(seed)` Same as `rand` but uses `seed` for a new sequence of pseudo random numbers.

Memory management

`malloc(size)` Allocates space for an object with size *size*. The allocated space is not initialized. Returns a pointer to the allocated space.

`aligned_alloc(alignment, size)` (C11 only) Allocates space for an object whose alignment is specified by *alignment* and with size *size*. The allocated space is not initialized. Returns a pointer to the allocated space.

`calloc(nobj, size)` Allocates space for *n* objects with size *size*. The allocated space is initialized with zeros. Returns a pointer to the allocated space.

`free(*ptr)` Deallocates the memory space pointed to by *ptr* which should be a pointer earlier returned by the `malloc` or `calloc` function.

`realloc(*ptr, size)` Deallocates the old object pointed to by *ptr* and returns a pointer to a new object with size *size*, while preserving its contents. If the new size is smaller than the old size, some contents at the end of the old region will be discarded. If the new size is larger than the old size, all of the old contents are preserved and any bytes in the new object beyond the size of the old object will have indeterminate values.

Environment communication

<code>abort()</code>	Causes abnormal program termination. If the signal SIGABRT is caught, the signal handler may take over control. (See Section 10.1.17, <i>signal.h</i>).
<code>atexit(*func)</code>	<i>func</i> points to a function that is called (without arguments) when the program normally terminates.
<code>exit(status)</code>	Causes normal program termination. Acts as if <code>main()</code> returns with <i>status</i> as the return value. <i>Status</i> can also be specified with the predefined macros EXIT_SUCCESS or EXIT_FAILURE.
<code>_Exit(status)</code>	Same as <code>exit</code> , but not registered by the <code>atexit</code> function or signal handlers registered by the <code>signal</code> function are called.
<code>at_quick_exit(*func)</code>	(C11 only) Registers the function pointed to by <i>func</i> to be called (without arguments) when <code>quick_exit</code> is called. Returns zero if the registration succeeds, nonzero if it fails.
<code>quick_exit(status)</code>	(C11 only) Causes normal program termination. Calls all functions registered by the <code>at_quick_exit</code> function, in the reverse order of their registration, and then calls <code>_Exit</code> .
<code>getenv(*s)</code>	Searches an environment list for a string <i>s</i> . Returns a pointer to the contents of <i>s</i> . NOTE: this function is not implemented because there is no OS.
<code>system(*s)</code>	Passes the string <i>s</i> to the environment for execution. NOTE: this function is not implemented because there is no OS.

Searching and sorting

<code>bsearch(*key, *base, n, size, *cmp)</code>	This function searches in an array of <i>n</i> members, for the object pointed to by <i>key</i> . The initial base of the array is given by <i>base</i> . The size of each member is specified by <i>size</i> . The given array must be sorted in ascending order, according to the results of the function pointed to by <i>cmp</i> . Returns a pointer to the matching member in the array, or NULL when not found.
<code>qsort(*base, n, size, *cmp)</code>	This function sorts an array of <i>n</i> members using the quick sort algorithm. The initial base of the array is given by <i>base</i> . The size of each member is specified by <i>size</i> . The array is sorted in ascending order, according to the results of the function pointed to by <i>cmp</i> .

Integer arithmetic

<code>int abs(j) long labs(j) long long llabs(j)</code>	Compute the absolute value of an <code>int</code> , <code>long int</code> , and <code>long long int j</code> respectively.
<code>div_t div(x,y) ldiv_t ldiv(x,y) lldiv_t lldiv(x,y)</code>	Compute x/y and $x\%y$ in a single operation. <i>X</i> and <i>y</i> have respectively type <code>int</code> , <code>long int</code> and <code>long long int</code> . The result is stored in the members <code>quot</code> and <code>rem</code> of struct <code>div_t</code> , <code>ldiv_t</code> and <code>lldiv_t</code> which have the same types.

Multibyte/wide character and string conversions

<code>mblen(*s, n)</code>	Determines the number of bytes in the multibyte character pointed to by <i>s</i> . At most <i>n</i> characters will be examined. (See also <code>mbrlen</code> in Section 10.1.30 , wchar.h).
<code>mbtowc(*pwc, *s, n)</code>	Converts the multibyte character in <i>s</i> to a wide character code and stores it in <i>pwc</i> . At most <i>n</i> characters will be examined.
<code>wctomb(*s, wc)</code>	Converts the wide character <i>wc</i> into a multibyte representation and stores it in the string pointed to by <i>s</i> . At most <code>MB_CUR_MAX</code> characters are stored.
<code>mbstowcs(*pwcs, *s, n)</code>	Converts a sequence of multibyte characters in the string pointed to by <i>s</i> into a sequence of wide characters and stores at most <i>n</i> wide characters into the array pointed to by <i>pwcs</i> . (See also <code>mbsrtowcs</code> in Section 10.1.30 , wchar.h).
<code>wcstombs(*s, *pwcs, n)</code>	Converts a sequence of wide characters in the array pointed to by <i>pwcs</i> into multibyte characters and stores at most <i>n</i> multibyte characters into the string pointed to by <i>s</i> . (See also <code>wcsrtowmb</code> in Section 10.1.30 , wchar.h).

10.1.25. stdnoreturn.h

This C11 header file contains the following macro definition:

```
#define noreturn _Noreturn
```

10.1.26. string.h and wchar.h

This header file provides numerous functions for manipulating strings. By convention, strings in C are arrays of characters with a terminating null character. Most functions therefore take arguments of type `*char`. However, many functions have also parallel wide character functions which take arguments of type `*wchar_t`. These functions are declared in `wchar.h`.

Copying and concatenation functions

string.h	wchar.h	Description
<code>memcpy(*s1, *s2, n)</code>	<code>wmemcpy(*s1, *s2, n)</code>	Copies <i>n</i> characters from <i>*s2</i> into <i>*s1</i> and returns <i>*s1</i> . If <i>*s1</i> and <i>*s2</i> overlap the result is undefined.
<code>memmove(*s1, *s2, n)</code>	<code>wmemmove(*s1, *s2, n)</code>	Same as <code>memcpy</code> , but overlapping strings are handled correctly. Returns <i>*s1</i> .
<code>strcpy(*s1, *s2)</code>	<code>wscpy(*s1, *s2)</code>	Copies <i>*s2</i> into <i>*s1</i> and returns <i>*s1</i> . If <i>*s1</i> and <i>*s2</i> overlap the result is undefined.
<code>strncpy(*s1, *s2, n)</code>	<code>wcsncpy(*s1, *s2, n)</code>	Copies not more than <i>n</i> characters from <i>*s2</i> into <i>*s1</i> and returns <i>*s1</i> . If <i>*s1</i> and <i>*s2</i> overlap the result is undefined.
<code>strcat(*s1, *s2)</code>	<code>wscat(*s1, *s2)</code>	Appends a copy of <i>*s2</i> to <i>*s1</i> and returns <i>*s1</i> . If <i>*s1</i> and <i>*s2</i> overlap the result is undefined.
<code>strncat(*s1, *s2, n)</code>	<code>wcsncat(*s1, *s2, n)</code>	Appends not more than <i>n</i> characters from <i>*s2</i> to <i>*s1</i> and returns <i>*s1</i> . If <i>*s1</i> and <i>*s2</i> overlap the result is undefined.

Comparison functions

string.h	wchar.h	Description
<code>memcmp(*s1, *s2, n)</code>	<code>wmemcmp(*s1, *s2, n)</code>	Compares the first <i>n</i> characters of <i>*s1</i> to the first <i>n</i> characters of <i>*s2</i> . Returns < 0 if <i>*s1</i> < <i>*s2</i> , 0 if <i>*s1</i> = <i>*s2</i> , or > 0 if <i>*s1</i> > <i>*s2</i> .
<code>strcmp(*s1, *s2)</code>	<code>wscmp(*s1, *s2)</code>	Compares string <i>*s1</i> to <i>*s2</i> . Returns < 0 if <i>*s1</i> < <i>*s2</i> , 0 if <i>*s1</i> = <i>*s2</i> , or > 0 if <i>*s1</i> > <i>*s2</i> .
<code>strncmp(*s1, *s2, n)</code>	<code>wcsncmp(*s1, *s2, n)</code>	Compares the first <i>n</i> characters of <i>*s1</i> to the first <i>n</i> characters of <i>*s2</i> . Returns < 0 if <i>*s1</i> < <i>*s2</i> , 0 if <i>*s1</i> = <i>*s2</i> , or > 0 if <i>*s1</i> > <i>*s2</i> .
<code>strcoll(*s1, *s2)</code>	<code>wscoll(*s1, *s2)</code>	Performs a local-specific comparison between string <i>*s1</i> and string <i>*s2</i> according to the LC_COLLATE category of the current locale. Returns < 0 if <i>*s1</i> < <i>*s2</i> , 0 if <i>*s1</i> = <i>*s2</i> , or > 0 if <i>*s1</i> > <i>*s2</i> . (See Section 10.1.13, locale.h)
<code>strxfrm(*s1, *s2, n)</code>	<code>wcsxfrm(*s1, *s2, n)</code>	Transforms (a local) string <i>*s2</i> so that a comparison between transformed strings with <code>strcmp</code> gives the same result as a comparison between non-transformed strings with <code>strcoll</code> . Returns the transformed string <i>*s1</i> .

Search functions

string.h	wchar.h	Description
<code>memchr(*s, c, n)</code>	<code>wmemchr(*s, c, n)</code>	Checks the first <i>n</i> characters of <i>*s</i> on the occurrence of character <i>c</i> . Returns a pointer to the found character.
<code>strchr(*s, c)</code>	<code>wcschr(*s, c)</code>	Returns a pointer to the first occurrence of character <i>c</i> in <i>*s</i> or the null pointer if not found.
<code>strrchr(*s, c)</code>	<code>wcsrchr(*s, c)</code>	Returns a pointer to the last occurrence of character <i>c</i> in <i>*s</i> or the null pointer if not found.
<code>strspn(*s, *set)</code>	<code>wcsspn(*s, *set)</code>	Searches <i>*s</i> for a sequence of characters specified in <i>*set</i> . Returns the length of the first sequence found.
<code>strcspn(*s, *set)</code>	<code>wcscspn(*s, *set)</code>	Searches <i>*s</i> for a sequence of characters <i>not</i> specified in <i>*set</i> . Returns the length of the first sequence found.
<code>strpbrk(*s, *set)</code>	<code>wcspbrk(*s, *set)</code>	Same as <code>strspn/wcsspn</code> but returns a pointer to the first character in <i>*s</i> that also is specified in <i>*set</i> .
<code>strstr(*s, *sub)</code>	<code>wcsstr(*s, *sub)</code>	Searches for a substring <i>*sub</i> in <i>*s</i> . Returns a pointer to the first occurrence of <i>*sub</i> in <i>*s</i> .
<code>strtok(*s, *dlm)</code>	<code>wcstok(*s, *dlm)</code>	A sequence of calls to this function breaks the string <i>*s</i> into a sequence of tokens delimited by a character specified in <i>*dlm</i> . The token found in <i>*s</i> is terminated with a null character. Returns a pointer to the first position in <i>*s</i> of the token.

Miscellaneous functions

string.h	wchar.h	Description
<code>memset(*s,c,n)</code>	<code>wmemset(*s,c,n)</code>	Fills the first <i>n</i> bytes of <i>*s</i> with character <i>c</i> and returns <i>*s</i> .
<code>strerror(errno)</code>	-	Typically, the values for <code>errno</code> come from <code>int errno</code> . This function returns a pointer to the associated error message. (See also Section 10.1.5, <code>errno.h</code>)
<code>strlen(*s)</code>	<code>wcslen(*s)</code>	Returns the length of string <i>*s</i> .

10.1.27. time.h and wchar.h

The header file `time.h` provides facilities to retrieve and use the (calendar) date and time, and the process time. Time can be represented as an integer value, or can be broken-down in components. Two arithmetic data types are defined which are capable of holding the integer representation of times:

```
clock_t unsigned long long
time_t unsigned long
```

The type `struct tm` below is defined according to ISO C99 with one exception: this implementation does not support leap seconds. The `struct tm` type is defines as follows:

```
struct tm
{
    int    tm_sec;        /* seconds after the minute - [0, 59]    */
    int    tm_min;        /* minutes after the hour - [0, 59]     */
    int    tm_hour;       /* hours since midnight - [0, 23]      */
    int    tm_mday;       /* day of the month - [1, 31]          */
    int    tm_mon;        /* months since January - [0, 11]     */
    int    tm_year;       /* year since 1900                     */
    int    tm_wday;       /* days since Sunday - [0, 6]          */
    int    tm_yday;       /* days since January 1 - [0, 365]     */
    int    tm_isdst;     /* Daylight Saving Time flag          */
};
```

Time manipulation

<code>clock</code>	Returns the application's best approximation to the processor time used by the program since it was started. This low-level routine is not implemented because it strongly depends on the hardware. To determine the time in seconds, the result of <code>clock</code> should be divided by the value defined by <code>CLOCKS_PER_SEC</code> .
<code>difftime(t1,t0)</code>	Returns the difference <i>t1-t0</i> in seconds.
<code>mktime(tm *tp)</code>	Converts the broken-down time in the structure pointed to by <i>tp</i> , to a value of type <code>time_t</code> . The return value has the same encoding as the return value of the <code>time</code> function.
<code>time(*timer)</code>	Returns the current calendar time. This value is also assigned to <i>*timer</i> .

Time conversion

- `asctime(tm *tp)` Converts the broken-down time in the structure pointed to by *tp* into a string in the form `Mon Feb 04 16:15:14 2013\n\0`. Returns a pointer to this string.
- `ctime(*timer)` Converts the calendar time pointed to by *timer* to local time in the form of a string. This is equivalent to: `asctime(localtime(timer))`
- `gmtime(*timer)` Converts the calendar time pointed to by *timer* to the broken-down time, expressed as UTC. Returns a pointer to the broken-down time.
- `localtime(*timer)` Converts the calendar time pointed to by *timer* to the broken-down time, expressed as local time. Returns a pointer to the broken-down time.

Formatted time

The next function has a parallel function defined in `wchar.h`:

time.h	wchar.h
<code>strftime(*s, smax, *fmt, tm *tp)</code>	<code>wcsftime(*s, smax, *fmt, tm *tp)</code>

Formats date and time information from `struct tm *tp` into *s* according to the specified format *fmt*. No more than *smax* characters are placed into *s*. The formatting of `strftime` is locale-specific using the `LC_TIME` category (see [Section 10.1.13, locale.h](#)).

You can use the next conversion specifiers:

- `%a` abbreviated weekday name
- `%A` full weekday name
- `%b` abbreviated month name
- `%B` full month name
- `%c` locale-specific date and time representation (same as `%a %b %e %T %Y`)
- `%C` last two digits of the year
- `%d` day of the month (01-31)
- `%D` same as `%m/%d/%y`
- `%e` day of the month (1-31), with single digits preceded by a space
- `%F` ISO 8601 date format: `%Y-%m-%d`
- `%g` last two digits of the week based year (00-99)
- `%G` week based year (0000–9999)
- `%h` same as `%b`
- `%H` hour, 24-hour clock (00-23)
- `%I` hour, 12-hour clock (01-12)
- `%j` day of the year (001-366)
- `%m` month (01-12)
- `%M` minute (00-59)

%n replaced by newline character
 %p locale's equivalent of AM or PM
 %r locale's 12-hour clock time; same as %I:%M:%S %p
 %R same as %H:%M
 %S second (00-59)
 %t replaced by horizontal tab character
 %T ISO 8601 time format: %H:%M:%S
 %u ISO 8601 weekday number (1-7), Monday as first day of the week
 %U week number of the year (00-53), week 1 has the first Sunday
 %V ISO 8601 week number (01-53) in the week-based year
 %w weekday (0-6, Sunday is 0)
 %W week number of the year (00-53), week 1 has the first Monday
 %x local date representation
 %X local time representation
 %y year without century (00-99)
 %Y year with century
 %z ISO 8601 offset of time zone from UTC, or nothing
 %Z time zone name, if any
 %% %

10.1.28. uchar.h

The C11 header file `uchar.h` declares types and functions for manipulating Unicode characters.

This header file declares the types:

`char16_t` Unsigned integer type used for 16-bit characters.
`char32_t` Unsigned integer type used for 32-bit characters.
`size_t` Unsigned integer type of the result of the `sizeof` operator.
`wchar_t` Integer type to represent character codes in large character sets.

The functions perform conversions between multibyte characters and Unicode characters. In these functions, `ps` points to struct `mbstate_t` which holds the conversion state information necessary to convert between sequences of multibyte characters and Unicode characters:

```
typedef struct
{
    wchar_t          wc_value; /* wide character value solved
                               so far */
    unsigned short   n_bytes; /* number of bytes of solved
                               multibyte */
    unsigned short   encoding; /* encoding rule for wide
```

```
character <=> multibyte
conversion */
} mbstate_t;
```

`mbrtoc16(*pc16, *s, n, *ps)` Converts a multibyte character *s* to a 16-bit character *pc16* according to conversion state *ps*.

`c16rtomb(*s, c16, *ps)` Converts a 16-bit character *c16* to a multibyte character according to conversion state *ps* and stores the multibyte character in *s*.

`mbrtoc32(*pc32, *s, n, *ps)` Converts a multibyte character *s* to a 32-bit character *pc32* according to conversion state *ps*.

`c32rtomb(*s, c32, *ps)` Converts a 32-bit character *c32* to a multibyte character according to conversion state *ps* and stores the multibyte character in *s*.

10.1.29. unistd.h

The file `unistd.h` contains standard UNIX I/O functions. These functions are all implemented using file system simulation. Except for `lstat` and `fstat` which are not implemented. This header file is not defined in ISO C99.

`access(*name, mode)` Use file system simulation to check the permissions of a file on the host. *mode* specifies the type of access and is a bit pattern constructed by a logical OR of the following values:

- `R_OK` Checks read permission.
- `W_OK` Checks write permission.
- `X_OK` Checks execute (search) permission.
- `F_OK` Checks to see if the file exists.

(*FSS implementation*)

`chdir(*path)` Use file system simulation to change the current directory on the host to the directory indicated by *path*. (*FSS implementation*)

`close(fd)` File close function. The given file descriptor should be properly closed. This function calls `_close()`. (*FSS implementation*)

`getcwd(*buf, size)` Use file system simulation to retrieve the current directory on the host. Returns the directory name. (*FSS implementation*)

`lseek(fd, offset, whence)` Moves read-write file offset. Calls `_lseek()`. (*FSS implementation*)

`read(fd, *buff, cnt)` Reads a sequence of characters from a file. This function calls `_read()`. (*FSS implementation*)

`stat(*name, *buff)` Use file system simulation to `stat()` a file on the host platform. (*FSS implementation*)

`lstat(*name, *buff)` This function is identical to `stat()`, except in the case of a symbolic link, where the link itself is 'stat'-ed, not the file that it refers to. (*Not implemented*)

`fstat(fd, *buff)` This function is identical to `stat()`, except that it uses a file descriptor instead of a name. (*Not implemented*)

`unlink(*name)` Removes the named file, so that a subsequent attempt to open it fails. (*FSS implementation*)

`write(fd, *buff, cnt)` Write a sequence of characters to a file. Calls `_write()`. (*FSS implementation*)

10.1.30. `wchar.h`

Many functions in `wchar.h` represent the wide character variant of other functions so these are discussed together. (See [Section 10.1.23, `stdio.h` and `wchar.h`](#), [Section 10.1.24, `stdlib.h` and `wchar.h`](#), [Section 10.1.26, `string.h` and `wchar.h`](#) and [Section 10.1.27, `time.h` and `wchar.h`](#)).

The remaining functions are described below. They perform conversions between multibyte characters and wide characters. In these functions, `ps` points to `struct mbstate_t` which holds the conversion state information necessary to convert between sequences of multibyte characters and wide characters:

```
typedef struct
{
    wchar_t          wc_value; /* wide character value solved
                               so far */
    unsigned short   n_bytes; /* number of bytes of solved
                               multibyte */
    unsigned short   encoding; /* encoding rule for wide
                               character <=> multibyte
                               conversion */
} mbstate_t;
```

When multibyte characters larger than 1 byte are used, this struct will be used to store the conversion information when not all the bytes of a particular multibyte character have been read from the source. In this implementation, multibyte characters are 1 byte long (`MB_CUR_MAX` and `MB_LEN_MAX` are defined as 1) and this will never occur.

`mbsinit(*ps)` Determines whether the object pointed to by `ps`, is an initial conversion state. Returns a non-zero value if so.

`mbsrtowcs(*pwcs, **src, n, *ps)` Restartable version of `mbstowcs`. See [Section 10.1.24, `stdlib.h` and `wchar.h`](#). The initial conversion state is specified by `ps`. The input sequence of multibyte characters is specified indirectly by `src`.

`wcsrtombs(*s, **src, n, *ps)` Restartable version of `wcstombs`. See [Section 10.1.24, `stdlib.h` and `wchar.h`](#). The initial conversion state is specified by `ps`. The input wide string is specified indirectly by `src`.

`mbrtowc(*pwc, *s, n, *ps)` Converts a multibyte character `*s` to a wide character `*pwc` according to conversion state `ps`. See also `mbtowc` in [Section 10.1.24, `stdlib.h` and `wchar.h`](#).

`wcrtomb(*s, wc, *ps)` Converts a wide character `wc` to a multibyte character according to conversion state `ps` and stores the multibyte character in `*s`.

`btowc(c)` Returns the wide character corresponding to character `c`. Returns `WEOF` on error.

`wctob(c)` Returns the multibyte character corresponding to the wide character *c*. The returned multibyte character is represented as one byte. Returns EOF on error.

`mbrlen(*s, n, *ps)` Inspects up to *n* bytes from the string **s* to see if those characters represent valid multibyte characters, relative to the conversion state held in **ps*.

10.1.31. wctype.h

Most functions in `wctype.h` represent the wide character variant of functions declared in `ctype.h` and are discussed in [Section 10.1.3, `ctype.h` and `wctype.h`](#). In addition, this header file provides extensible, locale specific functions and wide character classification.

`wctype(*property)` Constructs a value of type `wctype_t` that describes a class of wide characters identified by the string **property*. If *property* identifies a valid class of wide characters according to the `LC_TYPE` category (see [Section 10.1.13, `locale.h`](#)) of the current locale, a non-zero value is returned that can be used as an argument in the `iswctype` function.

`iswctype(wc, desc)` Tests whether the wide character *wc* is a member of the class represented by `wctype_t` *desc*. Returns a non-zero value if tested true.

Function	Equivalent to locale specific test
<code>iswalnum(wc)</code>	<code>iswctype(wc, wctype("alnum"))</code>
<code>iswalpha(wc)</code>	<code>iswctype(wc, wctype("alpha"))</code>
<code>iswcntrl(wc)</code>	<code>iswctype(wc, wctype("cntrl"))</code>
<code>iswdigit(wc)</code>	<code>iswctype(wc, wctype("digit"))</code>
<code>iswgraph(wc)</code>	<code>iswctype(wc, wctype("graph"))</code>
<code>iswlower(wc)</code>	<code>iswctype(wc, wctype("lower"))</code>
<code>iswprint(wc)</code>	<code>iswctype(wc, wctype("print"))</code>
<code>iswpunct(wc)</code>	<code>iswctype(wc, wctype("punct"))</code>
<code>iswspace(wc)</code>	<code>iswctype(wc, wctype("space"))</code>
<code>iswupper(wc)</code>	<code>iswctype(wc, wctype("upper"))</code>
<code>iswxdigit(wc)</code>	<code>iswctype(wc, wctype("xdigit"))</code>

`wctrans(*property)` Constructs a value of type `wctype_t` that describes a mapping between wide characters identified by the string **property*. If *property* identifies a valid mapping of wide characters according to the `LC_TYPE` category (see [Section 10.1.13, `locale.h`](#)) of the current locale, a non-zero value is returned that can be used as an argument in the `towctrans` function.

`towctrans(wc, desc)` Transforms wide character *wc* into another wide character, described by *desc*.

Function	Equivalent to locale specific transformation
<code>towlower(wc)</code>	<code>towctrans(wc, wctrans("tolower"))</code>

Function	Equivalent to locale specific transformation
<code>toupper(wc)</code>	<code>towctrans(wc, wctrans("toupper"))</code>

10.2. C Library Reentrancy

Some of the functions in the C library are reentrant, others are not. The table below shows the functions in the C library, and whether they are reentrant or not. A dash means that the function is reentrant. Note that some of the functions are not reentrant because they set the global variable 'errno' (or call other functions that eventually set 'errno'). If your program does not check this variable and errno is the only reason for the function not being reentrant, these functions can be assumed reentrant as well.

The explanation of the cause why a function is not reentrant sometimes refers to a footnote because the explanation is too lengthy for the table.

Function	Not reentrant because
<code>_close</code>	Uses global File System Simulation buffer, <code>_dbg_request</code>
<code>_doflt</code>	Uses I/O functions which modify <code>iob[]</code> . See (1).
<code>_doprint</code>	Uses indirect access to static <code>iob[]</code> array. See (1).
<code>_doscan</code>	Uses indirect access to <code>iob[]</code> and calls <code>ungetc</code> (access to local static <code>ungetc[]</code> buffer). See (1).
<code>_Exit</code>	See <code>exit</code> .
<code>_filbuf</code>	Uses <code>iob[]</code> , which is not reentrant. See (1).
<code>_flsbuf</code>	Uses <code>iob[]</code> . See (1).
<code>_getflt</code>	Uses <code>iob[]</code> . See (1).
<code>_iob</code>	Defines static <code>iob[]</code> . See (1).
<code>_lseek</code>	Uses global File System Simulation buffer, <code>_dbg_request</code>
<code>_open</code>	Uses global File System Simulation buffer, <code>_dbg_request</code>
<code>_read</code>	Uses global File System Simulation buffer, <code>_dbg_request</code>
<code>_unlink</code>	Uses global File System Simulation buffer, <code>_dbg_request</code>
<code>_write</code>	Uses global File System Simulation buffer, <code>_dbg_request</code>
<code>abort</code>	Calls <code>exit</code>
<code>abs labs llabs</code>	-
<code>access</code>	Uses global File System Simulation buffer, <code>_dbg_request</code>
<code>acos acosf acosl</code>	Sets <code>errno</code> .
<code>acosh acoshf acoshl</code>	Sets <code>errno</code> via calls to other functions.
<code>aligned_alloc</code>	See <code>malloc</code> (5).
<code>asctime</code>	<code>asctime</code> defines static array for broken-down time string.
<code>asin asinf asinl</code>	Sets <code>errno</code> .
<code>asinh asinhf asinhl</code>	Sets <code>errno</code> via calls to other functions.

Function	Not reentrant because
at_quick_exit	at_quick_exit defines static array with function pointers to execute when quick_exit is called.
atan atanf atanl	-
atan2 atan2f atan2l	-
atanh atanhf atanh1	Sets errno via calls to other functions.
atexit	atexit defines static array with function pointers to execute at exit of program.
atof	-
atoi	-
atol	-
bsearch	-
btowc	-
c16rtomb	Sets errno. Uses static internal_state variable.
c32rtomb	Sets errno. Uses static internal_state variable.
cabs cabsf cabsl	Sets errno via calls to other functions.
cacos cacosf cacosl	Sets errno via calls to other functions.
cacosh cacosh cfacosh1	Sets errno via calls to other functions.
calloc	calloc uses static buffer management structures. See malloc (5).
carg cargf cargl	-
casin casinl	Sets errno via calls to other functions.
casinh casinh cfasinh1	Sets errno via calls to other functions.
catan catanf catanl	Sets errno via calls to other functions.
catanh catanhf catanh1	Sets errno via calls to other functions.
cbrt cbrtf cbrtl	-
ccos ccosf ccosl	Sets errno via calls to other functions.
ccosh ccoshf ccosh1	Sets errno via calls to other functions.
ceil ceilf ceill	-
cexp cexpf cexpl	Sets errno via calls to other functions.
chdir	Uses global File System Simulation buffer, _dbg_request
cimag cimagf cimagl	-
cleanup	Calls fclose. See (1)
clearerr	Modifies iob[]. See (1)
clock	Uses global File System Simulation buffer, _dbg_request
clog clogf clogl	Sets errno via calls to other functions.
close	Calls _close
conj conjf conjl	-

Function	Not reentrant because
copysign copysignf copysignl	-
cos cosf cosl	-
cosh coshf coshl	cosh calls exp(), which sets errno. If errno is discarded, cosh is reentrant.
cpow cpowf cpowl	Sets errno via calls to other functions.
cproj cprojf cprojl	-
creal crealf creall	-
csin csinf csinl	Sets errno via calls to other functions.
csinh csinhf csinhl	Sets errno via calls to other functions.
csqrt csqrtf csqrtl	Sets errno via calls to other functions.
ctan ctanf ctanl	Sets errno via calls to other functions.
ctanh ctanhf ctanh1	Sets errno via calls to other functions.
ctime	Calls asctime
difftime	-
div ldiv lldiv	-
erf erfl erff	-
erfc erfcl erfcl	-
exit	Calls fclose indirectly which uses iob[] calls functions in _atexit array. See (1). To make exit reentrant kernel support is required.
exp expf expl	Sets errno.
exp2 exp2f exp2l	Sets errno.
expm1 expm1f expm1l	Sets errno via calls to other functions.
fabs fabsf fabsl	-
fclose	Uses values in iob[]. See (1).
fdim fdimf fdiml	-
feclearexcept	Writes PSW bits.
fegetenv	- (reads PSW bits)
fegetexceptflag	- (reads PSW bits via calls to other functions)
fegetround	- (reads PSW bits)
feholdexcept	Reads/writes PSW bits via calls to other functions.
feof	Uses values in iob[]. See (1).
feraiseexcept	Writes PSW bits.
ferror	Uses values in iob[]. See (1).
fesetenv	Writes PSW bits.
fesetexceptflag	Writes PSW bits via calls to other functions.

Function	Not reentrant because
fesetround	Writes PSW bits.
fetestexcept	- (reads PSW bits)
feupdateenv	Writes PSW bits via calls to other functions.
fflush	Modifies iob[]. See (1).
fgetc fgetc	Uses pointer to iob[]. See (1).
fgetpos	Sets the variable errno and uses pointer to iob[]. See (1) / (2).
fgets fgets	Uses iob[]. See (1).
floor floorf floorl	-
fma fmaf fmal	-
fmax fmaxf fmaxl	-
fmin fminf fminl	-
fmod fmodf fmodl	-
fopen	Uses iob[] and calls malloc when file open for buffered IO. See (1)
fpclassify	-
fprintf fwprintf	Uses iob[]. See (1).
fputc fputc	Uses iob[]. See (1).
fputs fputs	Uses iob[]. See (1).
fread	Calls fgetc. See (1).
free	free uses static buffer management structures. See malloc (5).
freopen	Modifies iob[]. See (1).
frexp frexpf frexpl	-
fscanf fwscanf	Uses iob[]. See (1)
fseek	Uses iob[] and calls _lseek. Accesses ungetc[] array. See (1).
fsetpos	Uses iob[] and sets errno. See (1) / (2).
fstat	<i>(Not implemented)</i>
ftell	Uses iob[] and sets errno. Calls _lseek. See (1) / (2).
fwrite	Uses iob[]. See (1).
fgetc fgetc	Uses iob[]. See (1).
fgetchar fgetwchar	Uses iob[]. See (1).
fgetcwd	Uses global File System Simulation buffer, _dbg_request
getenv	Skeleton only.
gets gets	Uses iob[]. See (1).
gmtime	gmtime defines static structure
hypot hypotf hypotl	Sets errno via calls to other functions.
ilogb ilogbf ilogbl	Sets errno.

Function	Not reentrant because
imaxabs	-
imaxdiv	-
isalnum iswalnum	-
isalpha iswalpha	-
isascii iswascii	-
iscntrl iswcntrl	-
isdigit iswdigit	-

<code>unlink</code>	Uses global File System Simulation buffer, <code>_dbg_request</code>
<code>vfprintf vfwprintf</code>	Uses <code>iob[]</code> . See (1).
<code>vfscanf vfwscanf</code>	Calls <code>_doscan</code>
<code>vprintf vwprintf</code>	Uses <code>iob[]</code> . See (1).
<code>vscanf vwscanf</code>	Calls <code>_doscan</code>
<code>vsprintf vswprintf</code>	Sets <code>errno</code> .
<code>vsscanf vswscanf</code>	Sets <code>errno</code> .
<code>wcrtomb</code>	Sets <code>errno</code> . Uses static <code>internal_state</code> variable.
<code>wcsrtoombs</code>	Sets <code>errno</code> .
<code>wcstoimax</code>	Sets <code>errno</code> via calls to other functions.
<code>wcstombs</code>	N.A.; skeleton function
<code>wcstoumax</code>	Sets <code>errno</code> via calls to other functions.
<code>wctob</code>	-
<code>wctomb</code>	N.A.; skeleton function
<code>wctrans</code>	-
<code>wctype</code>	-

Function	Not reentrant because
<code>write</code>	Calls <code>_write</code>

Table: C library reentrancy

Several functions in the C library are not reentrant due to the following reasons:

- The `iob[]` structure is static. This influences all I/O functions.
- The `ungetc[]` array is static. This array holds the characters (one for each stream) when `ungetc()` is called.
- The variable `errno` is globally defined. Numerous functions read or modify `errno`
- `_doprint` and `_doscan` use static variables for e.g. character counting in strings.
- Some string functions use locally defined (static) buffers. This is prescribed by ANSI.
- `malloc` uses a static heap space.

The following description discusses these items in more detail. The numbers at the beginning of each paragraph relate to the number references in the table above.

(1) *iob structures*

The I/O part of the C library is not reentrant by design. This is mainly caused by the static declaration of the `iob[]` array. The functions which use elements of this array access these elements via pointers (`FILE *`).

Building a multi-process system that is created in one link-run is hard to do. The C language scoping rules for external variables make it difficult to create a private copy of the `iob[]` array. Currently, the `iob[]` array has external scope. Thus it is visible in every module involved in one link phase. If these modules comprise several tasks (processes) in a system each of which should have its private copy of `iob[]`, it is apparent that the `iob[]` declaration should be changed. This requires adaptation of the library to the multi-tasking environment. The library modules must use a process identification as an index for determining which `iob[]` array to use. Thus the library is suitable for interfacing to that kernel only.

Another approach for the `iob[]` declaration problem is to declare the array static in one of the modules which create a task. Thus there can be more than one `iob[]` array in the system without having conflicts at link time. This brings several restrictions: Only the module that holds the declaration of the static `iob[]` can use the standard file handles `stdin`, `stdout` and `stderr` (which are the first three entries in `iob[]`). Thus all I/O for these three file handles should be located in one module.

(2) *errno declaration*

Several functions in the C library set the global variable `errno`. After completion of the function the user program may consult this variable to see if some error occurred. Since most of the functions that set `errno` already have a return type (this is the reason for using `errno`) it is not possible to check successful completion via the return type.

The library routines can set `errno` to the values defined in `errno.h`. See the file `errno.h` for more information.

`errno` can be set to `ERR_FORMAT` by the `print` and `scan` functions in the C library if you specify illegal format strings.

`errno` will never be set to `ERR_NOLONG` or `ERR_NOPOINT` since the C library supports long and pointer conversion routines for input and output.

`errno` can be set to `ERANGE` by the following functions: `exp()`, `strtol()`, `strtoul()` and `tan()`. These functions may produce results that are out of the valid range for the return type. If so, the result of the function will be the largest representable value for that type and `errno` is set to `ERANGE`.

`errno` is set to `EDOM` by the following functions: `acos()`, `asin()`, `log()`, `pow()` and `sqrt()`. If the arguments for these functions are out of their valid range (e.g. `sqrt(-1)`), `errno` is set to `EDOM`.

`errno` can be set to `ERR_POS` by the file positioning functions `ftell()`, `fsetpos()` and `fgetpos()`.

(3) `ungetc`

Currently the `ungetc` buffer is static. For each file entry in the `iob[]` structure array, there is one character available in the buffer to `ungetc` a character.

(4) `local buffers`

`tmpnam()` creates a temporary filename and returns a pointer to a local static buffer. This is according to the ANSI definition. Changing this function such that it creates the name in a user specified buffer requires another calling interface. Thus the function would be no longer portable.

`strtok()` scans through a string and remembers that the string and the position in the string for subsequent calls. This function is not reentrant by design. Making it reentrant requires support of a kernel to store the information on a per process basis.

`rand()` generates a sequence of random numbers. The function uses the value returned by a previous call to generate the next value in the sequence. This function can be made reentrant by specifying the previous random value as one of the arguments. However, then it is no longer a standard function.

(5) `malloc`

`Malloc` uses a heap space which is assigned at `locate` time. Thus this implementation is not reentrant. Making a reentrant `malloc` requires some sort of system call to obtain free memory space on a per process basis. This is not easy to solve within the current context of the library. This requires adaptation to a kernel.

This paragraph on reentrancy applies to multi-process environments only. If reentrancy is required for calling library functions from an exception handler, another approach is required. For such a situation it is of no use to allocate e.g. multiple `iob[]` structures. In such a situation several pieces of code in the library have to be declared 'atomic': this means that interrupts have to be disabled while executing an atomic piece of code.

Chapter 11. List File Formats

This chapter describes the format of the assembler list file and the linker map file.

11.1. Assembler List File Format

The assembler list file is an additional output file of the assembler that contains information about the generated code. For details on how to generate a list file, see [Section 4.4, *Generating a List File*](#).

The list file consists of a page header and a source listing.

Page header

The page header is repeated on every page:

```
TASKING VX-toolset for MCS: MCS assembler vx.yrz Build yymnddgg
Title                                                                 Page 1
```

```
ADDR CODE      CYCLES  LINE SOURCE LINE
```

The first line contains version information. The second line can contain a title which you can specify with the assembler control `$TITLE` and always contains a page number. The third line is empty and the fourth line contains the headings of the columns for the source listing.

With the assembler controls `$LIST ON/OFF`, `$PAGE`, and with the [assembler option `--list-format`](#) you can format the list file.

Source listing

The following is a sample part of a listing. An explanation of the different columns follows below.

```
ADDR CODE      CYCLES  LINE SOURCE LINE
                1           ; Module start
                .
                .
0000           33           .sdecl  '.mcstext.proc.channell',code
                34           .sect   '.mcstext.proc.channell'
                35
                36           .global process_channell
0000           37 process_channell: .type   func
0000 rrrr01A3  2     2     38           mrd    R3,chan1_par0

                .
                .
0008           44 buf:    .space  4
  | RESERVED
0017
```

TASKING VX-toolset for MCS User Guide

ADDR	This column contains the memory address. The address is a hexadecimal number that represents the offset from the beginning of a relocatable section or the absolute address for an absolute section. The address only appears on lines that generate object code.
CODE	This is the object code generated by the assembler for this source line, displayed in hexadecimal format. The displayed code need not be the same as the generated code that is entered in the object module. The code can also be relocatable code. In this case the letter 'r' is printed for the relocatable code part in the listing. For lines that allocate space, the code field contains the text "RESERVED". For lines that initialize a buffer, the code field lists one value followed by the word "REPEATS".
CYCLES	The first number in this column is the number of instruction cycles needed to execute the instruction(s) as generated in the CODE field. The second number is the accumulated cycle count of this section.
LINE	This column contains the line number. This is a decimal number indicating each input line, starting from 1 and incrementing with each source line.
SOURCE LINE	This column contains the source text. This is a copy of the source line from the assembly source file.

For the `.SET` and `.EQU` directives the `ADDR` and `CODE` columns do not apply. The symbol value is listed instead.

11.2. Linker Map File Format

The linker map file is an additional output file of the linker that shows how the linker has mapped the sections and symbols from the various object files (`.o`) to output sections. The locate part shows the absolute position of each section. External symbols are listed per space with their absolute address, both sorted on symbol and sorted on address. For details on how to generate a map file, see [Section 5.9, Generating a Map File](#).

With the linker option `--map-file-format` you can specify which parts of the map file you want to see.

In Eclipse the linker map file (`project.map.xml`) is generated in the output directory of the build configuration, usually `Debug` or `Release`. You can open the map file by double-clicking on the file name.

Each page displays a part of the map file. You can use the drop-down list or the Outline view to navigate through the different tables and you can use the following buttons.

Icon	Action	Description
	Back	Goes back one page in the history list.
	Forward	Goes forward one page in the history list.
	Next Table	Shows the next table from the drop-down list.
	Previous Table	Shows the previous table from the drop-down list.

When you right-click in the view, a popup menu appears (for example, to reset the layout of a table). The meaning of the different parts is:

Tool and Invocation

This part of the map file contains information about the linker, its version header information, binary location and which options are used to call it.

Used Resources

This part of the map file shows the memory usage at memory level and space level. The largest free block of memory (`Largest gap`) is also shown. This part also contains an estimation of the stack usage.

Explanation of the columns:

TASKING VX-toolset for MCS User Guide

Memory	The names of the memory as defined in the linker script file (* .lsl).
Code	The size of all executable sections.
Data	The size of all non-executable sections (not including stacks, heaps, debug sections in non-alloc space).
Reserved	The total size of reserved memories, reserved ranges, reserved special sections, stacks, heaps, alignment protections, sections located in non-alloc space (debug sections). In fact, this size is the same as the size in the Total column minus the size of all other columns.
Free	The free memory area addressable by this core. This area is accessible for unrestricted items.
Total	The total memory area addressable by this core.
Space	The names of the address spaces as defined in the linker script file (* .lsl). The names are constructed of the <code>derivative</code> name followed by a colon ':', the <code>core</code> name, another colon ':' and the <code>space</code> name. For example: <code>gtm31_02:mcs00:mcs.</code>
Native used ...	The size of sections located in this space.
Foreign used	The size of all sections destined for/located in other spaces, but because of overlap in spaces consume memory in this space.
Stack Name	The name(s) of the stack(s) as defined in the linker script file (* .lsl).
Used	An estimation of the stack usage. The linker calculates the required stack size by using information (<code>.CALLS</code> directives) generated by the compiler. If for example recursion is detected, the calculated stack size is inaccurate, therefore this is an estimation only. The calculated stack size is supposed to be smaller than the actual allocated stack size. If that is not the case, then a warning is given.
Recursive	Indicates if recursion is detected yes or no.
Entry Points	A list of entry points used for estimation of the stack usage.

Processed Files

This part of the map file shows all processed files. This also includes object files that are extracted from a library, with the symbol that led to the extraction.

Link Result

This part of the map file shows per object file how the link phase has mapped the sections from the various object files (`.o`) to output sections.

[in] File	The name of an input object file.
[in] Section	A section name and id from the input object file. The number between '(' ')' uniquely identifies the section.
[in] Size	The size of the input section.
[out] Offset	The offset relative to the start of the output section.
[out] Section	The resulting output section name and id.

[out] Size The size of the output section.

Module Local Symbols

This part of the map file shows a table for each local scope within an object file. Each table has three columns, 1 the symbol name, 2 the address of the symbol and 3 the space where the symbol resides in. The table is sorted on symbol name within each space.

By default this part is not shown in the map file. You have to turn this part on manually with linker option `--map-file-format=+statics` (module local symbols).

Cross References

This part of the map file lists all symbols defined in the object modules and for each symbol the object modules that contain a reference to the symbol are shown. Also, symbols that remain undefined are shown.

Call Graph

This part of the map file contains a schematic overview that shows how (library) functions call each other. To obtain call graph information, the assembly file must contain `.CALLS` directives.

The following example is a part of a call graph in the textual version of the map file (`.map`):

```
__START [4,116]
|
|-- main [8,112]
|   |
|   |-- printf [16,104]
|       |
|       |-- _doprint [24,88]
|           |
|           |-- _io_putc [4,64]
|               |
|               |-- fputc [4,60]
|                   |
|                   |-- _flsbuf [20,56]
|                       |
|                       |-- _fflush *
|                           |
|                           |-- _host_write *
|
|-- exit [stack_0:8,68]

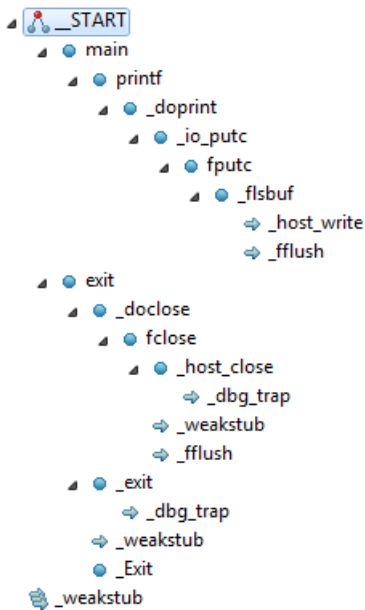

* _dbg_trap [stack_0:0,0]
```

- A * after a function name indicates that the call tree starting with this function is shown separately, with a * in front of the function name.

TASKING VX-toolset for MCS User Guide

- A * in front of a function name indicates that the function is not considered a "root" in the call graph since it is called by one or more other functions.
- An additional R (not shown in this example) indicates this function is part of a recursive call chain. If both a leaf and the root of a tree are marked this way, all nodes in between are in a recursive chain.
- An '__INDIRECT__' entry (not shown in this example) indicates an indirect function call. It is not an actual function. Each function listed as a caller of the __INDIRECT__ placeholder symbol places a call through a function pointer. Each function listed as a callee of the __INDIRECT__ placeholder symbol has its address taken (and used).
- [] after a function contains information about the stack usage. The first field is the amount of stack used by the function and the second field is the amount of stack used by the function including its callees.

In the graphical version of the map file, you can expand or collapse a single node. Use the  /  buttons to expand/collapse all nodes in the call graph. Hover the mouse over a function (root, callee or node) to see information about the stack usage.

Icon	Meaning	Description
	Root	This function is the top of the call graph. If there are interrupt handlers, there can be several roots.
	Callee	This function is referenced by several caller functions. Right-click on the function and select Expand all References to see all functions that reference this function. Select Back to Caller to return to the calling function. ⁹ indicates a recursive function.

Icon	Meaning	Description
	Node	A normal node (function) in the call graph.
 	Caller	This function calls a function which is listed separately in the call graph. Right-click on the function and select Go to Callee to see the callee. Hover the mouse over the function to see a popup with all callees. ↻ indicates a recursive function.

Overlay

This part is empty for the MCS.

Locate Result: Sections

This part of the map file shows the absolute position of each section in the absolute object file. It is organized per address space, memory chip and group and sorted on space address. In Eclipse, right-click in the table and select **Configure Columns** to specify which columns you want to see. If you hover the mouse over a section, you get a popup with information about the section. If you select a range of sections, in the Fast View bar (at the bottom) you will see information about the selected range, such as the total size, how many sections are selected and how many gaps are present.

#	The line number and default sort order.
Section	The name and id of the section. The number between '()' uniquely identifies the section. Sections within square brackets [] will be copied during initialization from ROM to the corresponding section name in RAM.
Section name	
Section number	
Sect. size (hex)	The size of the section in minimum addressable units (hexadecimal or decimal).
Sect. size (dec)	
Group	Sections can be ordered in groups. These are the names of the groups as defined in the linker script file (*.lsl) with the keyword <code>group</code> in the <code>section_layout</code> definition. The name that is displayed is the name of the deepest nested group.
Start address	The first address of the section in the address space.
End address	The last address of the section in the address space.
Symbols in sect.	The names of the external symbols that are referenced in the section. See Locate Result: Symbols below.
Defined in	The names of the input modules the section is defined in. See Link Result: [in] File above.
Referenced in	The names of the modules that contain a reference to the section. See Cross References above.
Address space	The name of the address space.
Chip name	The names of the memory chips as defined in the linker script file (*.lsl) in the <code>memory</code> definitions.
Chip addr	The absolute offset of the section from the start of a memory chip.
Locate type:properties	The locate rule type and properties. See Locate Rules below.

The following buttons are available in this part of the map file.

Icon	Action	Description
	Configure Section Filter	Opens the Configure Section Filter dialog. Here you can select which sections you want to see in the map file and how.
	Enable Highlighting	All sections that are marked with "Highlight" in the Configure Section Filter dialog will be highlighted in the table.
	Enable Collapsing	All sections that are marked with "Collapse" in the Configure Section Filter dialog will appear collapsed in the table.
	Only Show Matching Lines	All lines that are not part of the selection in the Configure Section Filter dialog will be hidden.
	Show Gaps	Also shows the gaps in the map file. Click the button again to hide the gaps.

Configure Section Filter Dialog

In this dialog you can filter which sections you want to see in the map file and how. Click **Add** to add a new filter. Explanation of the columns and fields:

Highlight	Marks the section as a candidate for highlighting. Turn on Enable Highlighting to see the effect.
Color	The highlight color.
Collapse	Marks the section as a candidate for collapsing. Turn on Enable Collapsing to see the effect.
Section name	A filter to select a section or group of sections. Wildcards are allowed. Wildcards follow the rules of regular expressions. To get help on which wildcards are supported, press Ctrl-space . Click an item in the list for help, double-click to add the wildcard.
Start address	The first address of the section in the address space for this filter.
End address	The last address of the section in the address space for this filter.
Address space	The name of the address space.
Chip name	The name of the memory chip as defined in the linker script file (*.lsl) in the memory definitions.
Hide gaps smaller than	If gaps are shown in the map file, here you can limit the number of gaps you want to see.

The meaning of the check boxes is the same as the corresponding buttons available in this part of the map file.

Locate Result: Symbols

This part of the map file lists all external symbols per address space name.

Address	The absolute address of the symbol in the address space.
Name	The name of the symbol.

Space The names of the address spaces as defined in the linker script file (`*.lsl`). The names are constructed of the `derivative` name followed by a colon `:`, the `core` name, another colon `:` and the `space` name. For example:
`gtm31_02:mcs00:mcs.`

Processor and Memory

This part of the map file shows the processor and memory information of the linker script file.

By default this part is not shown in the map file. You have to turn this part on manually with linker option `--map-file-format=+lsl` (processor and memory info). You can print this information to a separate file with linker option `--lsl-dump`.

You can expand or collapse a part of the information.

Locate Rules

This part of the map file shows the rules the linker uses to locate sections.

Address space The names of the address spaces as defined in the linker script file (`*.lsl`). The names are constructed of the `derivative` name followed by a colon `:`, the `core` name, another colon `:` and the `space` name.

Type The rule type:

`ordered/contiguous/clustered/unrestricted`

Specifies how sections are grouped. By default, a group is 'unrestricted' which means that the linker has total freedom to place the sections of the group in the address space.

`absolute`

The section must be located at the address shown in the Properties column.

`ranged`

The section must be located anywhere in the address ranges shown in the Properties column; end addresses are not included in the range.

`page`

The sections must be located in some address range with a size not larger than shown in the Properties column; the first number is the page size, the second part is the address range restriction within the page.

`ranged page`

Both the `ranged` and the `paged` restriction apply. In the Properties column the range restriction is listed first, followed by the `paged` restriction between parenthesis.

ballooned

After locating all sections, the largest remaining gap in the space is used completely for the stack and/or heap.

Properties

The contents depends on the Type column.

Prio

The locate priority of the rule. A higher priority value gives a rule precedence over a rule with a lower priority, but only if the two rules have the same type and the same properties. The relative order of rules of different types or different properties is not affected by this priority value. You can set the priority with the `priority group attribute` in LSL

Sections

The sections to which the rule applies;

restrictions between sections are shown in this column:

```
<  ordered
|  contiguous
+  clustered
```

For contiguous sections, the linker uses the section order as shown here. Clustered sections can be located in any relative order.

Removed Sections

This part of the map file shows the sections which are removed from the output file as a result of the optimization option to delete unreferenced sections and or duplicate code or constant data (`linker option --optimize=cxy`).

Section

The name of the section which has been removed.

File

The name of the input object file where the section is removed from.

Library

The name of the library where the object file is part of.

Symbol

The symbols that were present in the section.

Reason

The reason why the section has been removed. This can be because the section is unreferenced or duplicated.

Chapter 12. Object File Formats

The linker can generate machine code in several output formats: [ELF/DWARF](#), [Intel Hex](#), [Motorola S-records](#) and [C array](#). The C array format is a special one, where the generated machine code is in the form of C code. The following sections describe each format.

12.1. ELF/DWARF Object Format

The TASKING VX-toolset for MCS produces objects in the ELF/DWARF 3 format.

The ELF/DWARF Object Format for the MCS toolset follows the convention as described in the *MCS Embedded Application Binary Interface* [TASKING].

For a complete description of the ELF and DWARF formats, please refer to the *Tool Interface Standard (TIS)*.

12.2. Intel Hex Record Format

Intel Hex records describe the hexadecimal object file format for 8-bit, 16-bit and 32-bit microprocessors. The hexadecimal object file is an ASCII representation of an absolute binary object file. There are six different types of records:

- Data Record (8-, 16, or 32-bit formats)
- End of File Record (8-, 16, or 32-bit formats)
- Extended Segment Address Record (16, or 32-bit formats)
- Start Segment Address Record (16, or 32-bit formats)
- Extended Linear Address Record (32-bit format only)
- Start Linear Address Record (32-bit format only)

To generate an Intel Hex output file:

1. From the **Project** menu, select **Properties**
The Properties dialog appears.
2. In the left pane, expand **C/C++ Build** and select **Settings**.
In the right pane the Settings appear.
3. On the Tool Settings tab, select **Linker » Output Format**.
4. Enable the option **Generate Intel Hex format file**.
5. (Optional) Specify the **Size of addresses (in bytes) for Intel Hex records**.

6. (Optional) Enable or disable the option **Emit start address record**.

By default the linker generates records in the 32-bit format (4-byte addresses).

General Record Format

In the output file, the record format is:

:	<i>length</i>	<i>offset</i>	<i>type</i>	<i>content</i>	<i>checksum</i>
---	---------------	---------------	-------------	----------------	-----------------

where:

- :** is the record header.
- length* is the record length which specifies the number of bytes of the *content* field. This value occupies one byte (two hexadecimal digits). The linker outputs records of 255 bytes (32 hexadecimal digits) or less; that is, *length* is never greater than 0xFF.
- offset* is the starting load offset specifying an absolute address in memory where the data is to be located when loaded by a tool. This field is two bytes long. This field is only used for Data Records. In other records this field is coded as four ASCII zero characters ('0000').
- type* is the record type. This value occupies one byte (two hexadecimal digits). The record types are:

Byte Type	Record Type
00	Data
01	End of file
02	Extended segment address (not used)
03	Start segment address (not used)
04	Extended linear address (32-bit)
05	Start linear address (32-bit)

- content* is the information contained in the record. This depends on the record type.
- checksum* is the record checksum. The linker computes the checksum by first adding the binary representation of the previous bytes (from *length* to *content*). The linker then computes the result of sum modulo 256 and subtracts the remainder from 256 (two's complement). Therefore, the sum of all bytes following the header is zero.

Extended Linear Address Record

The Extended Linear Address Record specifies the two most significant bytes (bits 16-31) of the absolute address of the first data byte in a subsequent Data Record:

:	02	0000	04	<i>upper_address</i>	<i>checksum</i>
---	----	------	----	----------------------	-----------------

```
:04000005000004A44F
| | | | | _ checksum
| | | | | _ address
| | | | | _ type
| | _ offset
| _ length
```

End of File Record

The hexadecimal file always ends with the following end-of-file record:

```
:00000001FF
| | | | | _ checksum
| | | | | _ type
| | _ offset
| _ length
```

12.3. Motorola S-Record Format

To generate a Motorola S-record output file:

1. From the **Project** menu, select **Properties**
The Properties dialog appears.
2. In the left pane, expand **C/C++ Build** and select **Settings**.
In the right pane the Settings appear.
3. On the Tool Settings tab, select **Linker » Output Format**.
4. Enable the option **Generate S-records file**.
5. (Optional) Specify the **Size of addresses (in bytes) for Motorola S records**.

By default, the linker produces output in Motorola S-record format with three types of S-records (4-byte addresses): S0, S3 and S7. Depending on the size of addresses you can force other types of S-records. They have the following layout:

S0 - record

S0	<i>length</i>	0000	<i>comment</i>	<i>checksum</i>
-----------	---------------	------	----------------	-----------------

A linker generated S-record file starts with an S0 record with the following contents:

```
l m c s
S00700006C6D637349
```

The S0 record is a comment record and does not contain relevant information for program execution.

where:

S0	is a comment record and does not contain relevant information for program execution.
<i>length</i>	represents the number of bytes in the record, not including the record type and length byte. This value occupies one byte (two hexadecimal digits).
<i>comment</i>	contains the name of the linker.
<i>checksum</i>	is the record checksum. The linker computes the checksum by first adding the binary representation of the bytes following the record type (starting with the <i>length</i> byte) to just before the checksum. Then the one's complement is calculated of this sum. The least significant byte of the result is the checksum. The sum of all bytes following the record type is 0xFF.

S1 / S2 / S3 - record

This record is the program code and data record for 2-byte, 3-byte or 4-byte addresses respectively.

S1	<i>length</i>	<i>address</i>	<i>code bytes</i>	<i>checksum</i>
S2	<i>length</i>	<i>address</i>	<i>code bytes</i>	<i>checksum</i>
S3	<i>length</i>	<i>address</i>	<i>code bytes</i>	<i>checksum</i>

where:

S1	is the program code and data record for 2-byte addresses.
S2	is the program code and data record for 3-byte addresses.
S3	is the program code and data record for 4-byte addresses (this is the default).
<i>length</i>	represents the number of bytes in the record, not including the record type and length byte. This value occupies one byte (two hexadecimal digits).
<i>address</i>	contains the code or data address.
<i>code bytes</i>	contains the actual program code and data.
<i>checksum</i>	is the record checksum. The checksum calculation is identical to S0.

Example:

```
S319000018D800000010080053A6040053A40C000025000004E0D5
| |                                     |_ checksum
| |                                     |_ code
| |_ address
|_ length
```

S7 / S8 / S9 - record

This record is the termination record for 4-byte, 3-byte or 2-byte addresses respectively.

TASKING VX-toolset for MCS User Guide

S7	<i>length</i>	<i>address</i>	<i>checksum</i>
S8	<i>length</i>	<i>address</i>	<i>checksum</i>
S9	<i>length</i>	<i>address</i>	<i>checksum</i>

where:

- S7** is the termination record for 4-byte addresses (this is the default). S7 is the corresponding termination record for S3 records.
- S8** is the termination record for 3-byte addresses. S8 is the corresponding termination record for S2 records.
- S9** is the termination record for 2-byte addresses. S9 is the corresponding termination record for S1 records.
- length* represents the number of bytes in the record, not including the record type and length byte. This value occupies one byte (two hexadecimal digits).
- address* contains the program start address.
- checksum* is the record checksum. The checksum calculation is identical to S0.

Example:

```
S705000004A452
| | |
| | | |__checksum
| | |
| | | |__ address
| | |
| | | |__ length
```

12.4. C Array Format

The linker can emit the generated machine code in the form of C code. This is useful for the integration of MCS code in applications where the CPU is programmed with a non-TASKING compiler. Note that no symbolic debugging is possible unless you use the debug information from the ELF file.

The C array output format consists of a C source file with data encoded in a C array initializer combined with a C header file that contains necessary declarations and optionally provides access to the exported symbols of the program. You can use the C array format only for chip output files where, as with normal hex files, each memory gets its own output file that contains data for that memory only. The intended target for output files in C array format is a programmable peripheral where an application compiled for the peripheral is imported into a host application as C code. This "host application" must initialize the programmable peripheral's memory using the data in the C array(s).

Generate the C array output format

To generate a C array output file on the command line use [linker option](#) `--chip-output=basename:CARR:32`. For example with the following call to the control program:

```
ccms -Cgtm31_02 -t --chip-output=myproject:CARR:32 myproject.c
```

This results in the files `myproject_gtm31_02_mcs00.c` and `myproject_gtm31_02_mcs00.h`, where the basename is appended with an underscore and the full name of the memory represented in the file.

To generate a C array output file in the Eclipse IDE:

1. From the **Project** menu, select **Properties**
The Properties dialog appears.
2. In the left pane, expand **C/C++ Build** and select **Settings**.
In the right pane the Settings appear.
3. On the Tool Settings tab, select **Linker » Output Format**.
4. Enable the option **Generate C array file**.
5. (Optional) Enable the option **Emit list of exported symbols**.

C array source file

The C array source file contains an initialized array with the data of the memory. Each non-zero element of the C array corresponds to an assembled instruction or an initialized memory mapped variable. The array starts with the first initialized Minimal Addressable Unit (MAU) in the memory and ends with the last initialized MAU in the same memory. Any non-initialized MAUs in between are assigned the value 0. Sections that are marked as clear are emitted as zero values. Sections that are marked as scratch will not appear in the C array output unless they occupy space between initialized/cleared sections.

Example (part of) output of a C array source file:

```
#include "myproject_gtm31_02_mcs00.h"
unsigned long myproject_gtm31_02_mcs00[] = {
    0xE00004AC, /* 0 */
    0xE0000004, /* 1 */
    0xE0000008, /* 2 */
    0xE000000C, /* 3 */
    0xE0000010, /* 4 */
    0xE0000014, /* 5 */
    0xE0000018, /* 6 */
    0xE000001C, /* 7 */
    0x00000000, /* 8 */
    0x00000000, /* 9 */
    0x00000012, /* 10 */
    ...
    0x00000000, /* 1450 */
    0x00000000, /* 1451 */
    0x00000000, /* 1452 */
};
```

By default the C array data elements have data type `unsigned long`. You can overrule this default with linker option `--c-array-element-type`.

C array header file

The C array header file contains a define for the offset from the start of the memory where the data array starts (in MAUs). Furthermore it contains a define for the size of the data array in MAUs of the memory and an `extern` declaration of the data array that is defined in the C source file.

Example output of a C array header file:

```
/* THIS IS A GENERATED FILE */
extern unsigned long myproject_gtm31_02_mcs00[];
#define OFFSET_MYPROJECT_GTM31_02_MCS00 0
#define SIZE_MYPROJECT_GTM31_02_MCS00 5812
```

The C array header file can also contain a list of preprocessor variable definitions for each label mentioned in the MCS application. With the linker option `--hex-format=+c-array-symbols` the linker emits a list of exported symbols in the header file for each "C array" output C source file. An exported symbol is represented by a preprocessor definition where the name is the full basename of the file translated to upper case and with colon(s) replaced by underscore(s), followed by an underscore and the name of the exported variable, while the value is the index of the variable's location in the data array. Symbols with a name that is not guaranteed to be a valid C identifier are emitted inside a comment block.

Example:

```
#define MYPROJECT_GTM31_02_MCS00_main 1357
#define MYPROJECT_GTM31_02_MCS00__START 299
#define MYPROJECT_GTM31_02_MCS00__lc_ub_stack_main 1381
#define MYPROJECT_GTM31_02_MCS00__doprint 321
#define MYPROJECT_GTM31_02_MCS00__printf_int2 321
#define MYPROJECT_GTM31_02_MCS00__printf 1333
#define MYPROJECT_GTM31_02_MCS00__Exit 296
#define MYPROJECT_GTM31_02_MCS00_myvar 10
/* #define MYPROJECT_GTM31_02_MCS00__vector.7_loop 7 */
/* #define MYPROJECT_GTM31_02_MCS00__vector.6_loop 6 */
/* #define MYPROJECT_GTM31_02_MCS00__vector.5_loop 5 */
/* #define MYPROJECT_GTM31_02_MCS00__vector.4_loop 4 */
/* #define MYPROJECT_GTM31_02_MCS00__vector.3_loop 3 */
/* #define MYPROJECT_GTM31_02_MCS00__vector.2_loop 2 */
/* #define MYPROJECT_GTM31_02_MCS00__vector.1_loop 1 */
#define MYPROJECT_GTM31_02_MCS00__lc_ub_stack_0 1381
```

If the C array is directly mapped to the MCS memory, the software of the host CPU can use these preprocessor variables for direct access of MCS program variables. For example, the host CPU could overwrite the value 0x12 of variable `myvar` with 0x14 using the following C code statement:

```
myproject_gtm31_02_mcs00[MYPROJECT_GTM31_02_MCS00_myvar] = 0x14;
```

Chapter 13. Linker Script Language (LSL)

To make full use of the linker, you can write a script with information about the architecture of the target processor and locating information. The language for the script is called the *Linker Script Language (LSL)*. This chapter first describes the structure of an LSL file. The next section contains a summary of the LSL syntax. In the remaining sections, the semantics of the Linker Script Language is explained.

The TASKING linker is a target independent linker/locator that can simultaneously link and locate all programs for all cores available on a target board. The target board may be of arbitrary complexity. A simple target board may contain one standard processor with some external memory that executes one task. A complex target board may contain multiple standard processors and DSPs combined with configurable IP-cores loaded in an FPGA. Each core may execute a different program, and external memory may be shared by multiple cores.

LSL serves two purposes. First it enables you to specify the characteristics (that are of interest to the linker) of your specific target board and of the cores installed on the board. Second it enables you to specify how sections should be located in memory.

13.1. Structure of a Linker Script File

A script file consists of several definitions. The definitions can appear in any order.

The architecture definition (required)

In essence an *architecture definition* describes how the linker should convert logical addresses into physical addresses for a given type of core. If the core supports multiple address spaces, then for each space the linker must know how to perform this conversion. In this context a physical address is an offset on a given internal or external bus. Additionally the architecture definition contains information about items such as the stack.

This specification is normally written by Altium. Altium supplies LSL files in the `include.lsl` directory. The architecture definition of the LSL file should not be changed by you unless you also modify the core's hardware architecture. If the LSL file describes a multi-core system an architecture definition must be available for each different type of core.

See [Section 13.4, *Semantics of the Architecture Definition*](#) for detailed descriptions of LSL in the architecture definition.

The derivative definition

The *derivative definition* describes the configuration of the internal (on-chip) bus and memory system. Basically it tells the linker how to convert offsets on the buses specified in the architecture definition into offsets in internal memory. Microcontrollers and DSPs often have internal memory and I/O sub-systems apart from one or more cores. The design of such a chip is called a *derivative*.

Altium provides LSL descriptions of supported derivatives. When you build an ASIC or use a derivative that is not (yet) supported by the TASKING tools, you may have to write a derivative definition.

When you want to use multiple cores of the same type, you must instantiate the cores in a derivative definition, since the linker automatically instantiates only a single core for an unused architecture.

See [Section 13.5, *Semantics of the Derivative Definition*](#) for a detailed description of LSL in the derivative definition.

The processor definition

The *processor definition* describes an instance of a derivative. Typically the processor definition instantiates one derivative only (single-core processor). A processor that contains multiple cores having the same (homogeneous) or different (heterogeneous) architecture can also be described by instantiating multiple derivatives of the same or different types in separate processor definitions.

See [Section 13.6, *Semantics of the Board Specification*](#) for a detailed description of LSL in the processor definition.

The memory and bus definitions (optional)

Memory and bus definitions are used within the context of a derivative definition to specify internal memory and on-chip buses. In the context of a board specification the memory and bus definitions are used to define external (off-chip) memory and buses. Given the above definitions the linker can convert a logical address into an offset into an on-chip or off-chip memory device.

See [Section 13.6.3, *Defining External Memory and Buses*](#), for more information on how to specify the external physical memory layout. *Internal* memory for a processor should be defined in the derivative definition for that processor.

The board specification

The processor definition and memory and bus definitions together form a *board specification*. LSL provides language constructs to easily describe single-core and heterogeneous or homogeneous multi-core systems. The board specification describes all characteristics of your target board's system buses, memory devices, I/O sub-systems, and cores that are of interest to the linker. Based on the information provided in the board specification the linker can for each core:

- convert a logical address to an offset within a memory device
- locate sections in physical memory
- maintain an overall view of the used and free physical memory within the whole system while locating

The section layout definition (optional)

The optional section layout definition enables you to exactly control where input sections are located. Features are provided such as: the ability to place sections at a given load-address or run-time address, to place sections in a given order, and to overlay code and/or data sections.

Which object files (sections) constitute the task that will run on a given core is specified on the command line when you invoke the linker. The linker will link and locate all sections of all tasks simultaneously. From the section layout definition the linker can deduce where a given section may be located in memory,

form the board specification the linker can deduce which physical memory is (still) available while locating the section.

See [Section 13.8, *Semantics of the Section Layout Definition*](#), for more information on how to locate a section at a specific place in memory.

Skeleton of a Linker Script File

```
architecture architecture_name
{
    // Specification core architecture
}

derivative derivative_name
{
    // Derivative definition
}

processor processor_name
{
    // Processor definition
}

memory and/or bus definitions

section_layout space_name
{
    // section placement statements
}
```

13.2. Syntax of the Linker Script Language

This section describes what the LSL language looks like. An LSL document is stored as a file coded in UTF-8 with extension `.lsl`. Before processing an LSL file, the linker preprocesses it using a standard C preprocessor. Following this, the linker interprets the LSL file using a scanner and parser. Finally, the linker uses the information found in the LSL file to guide the locating process.

13.2.1. Preprocessing

When the linker loads an LSL file, the linker first processes it with a C-style preprocessor. As such, it strips C and C++ comments. Lines starting with the `#` character are taken as commands for the preprocessor. You can use the standard ISO C99 preprocessor directives, including:

```
#include "file"
#include <file>
```

Preprocess and include file *file* at this point in the LSL file.

For example:

TASKING VX-toolset for MCS User Guide

```
#include "arch.lsl"
```

Preprocess and include the file `arch.lsl` at this point in the LSL file.

```
#if condition
#else
#endif
```

If the *condition* evaluates to a non-zero value, copy the following lines, up to an `#else` or `#endif` command, skip lines between `#else` and `#endif`, if present. If the condition evaluates to zero, skip the lines up to the `#else` command, or `#endif` if no `#else` is present, and copy the lines between the `#else` and `#endif` commands.

```
#ifdef identifier
#else
#endif
```

Same as `#if`, but with `defined(identifier)` as condition.

```
#error text
```

Causes a fatal error the given message (optional).

13.2.2. Lexical Syntax

The following lexicon is used to describe the syntax of the Linker Script Language:

$A ::= B$	=	A is defined as B
$A ::= B C$	=	A is defined as B and C ; B is followed by C
$A ::= B \mid C$	=	A is defined as B or C
$\langle B \rangle^{0 1}$	=	zero or one occurrence of B
$\langle B \rangle^{>=0}$	=	zero or more occurrences of B
$\langle B \rangle^{>=1}$	=	one or more occurrences of B
<i>IDENTIFIER</i>	=	a character sequence starting with 'a'-'z', 'A'-'Z' or '_'. Following characters may also be digits and dots '.'
<i>STRING</i>	=	sequence of characters not starting with <code>\n</code> , <code>\r</code> or <code>\t</code>
<i>DQSTRING</i>	=	" <i>STRING</i> " (double quoted string)
<i>OCT_NUM</i>	=	octal number, starting with a zero (06, 045)
<i>DEC_NUM</i>	=	decimal number, not starting with a zero (14, 1024)

HEX_NUM = hexadecimal number, starting with '0x' (0x0023, 0xFF00)

OCT_NUM, *DEC_NUM* and *HEX_NUM* can be followed by a **k** (kilo), **M** (mega), or **G** (giga).

Characters in **bold** are characters that occur literally. Words in *italics* are higher order terms that are defined in the same or in one of the other sections.

To write comments in LSL file, you can use the C style `/* */` or C++ style `//`.

13.2.3. Identifiers and Tags

```

arch_name ::= IDENTIFIER
bus_name ::= IDENTIFIER
core_name ::= IDENTIFIER
derivative_name ::= IDENTIFIER
file_name ::= DQSTRING
group_name ::= IDENTIFIER
heap_name ::= section_name
map_name ::= IDENTIFIER
mem_name ::= IDENTIFIER
proc_name ::= IDENTIFIER
section_name ::= DQSTRING
space_name ::= IDENTIFIER
stack_name ::= section_name
symbol_name ::= DQSTRING
tag_attr ::= (tag<,tag>>=0)
tag ::= tag = DQSTRING
    
```

A tag is an arbitrary text that can be added to a statement.

13.2.4. Expressions

The expressions and operators in this section work the same as in ISO C.

```

number ::= OCT_NUM
          | DEC_NUM
          | HEX_NUM

expr ::= number
        | symbol_name
        | unary_op expr
        | expr binary_op expr
        | expr ? expr : expr
        | ( expr )
        | function_call

unary_op ::= ! // logical NOT
           | ~ // bitwise complement
           | - // negative value
    
```

```
binary_op      ::= ^      // exclusive OR
                | *      // multiplication
                | /      // division
                | %      // modulus
                | +      // addition
                | -      // subtraction
                | >>     // right shift
                | <<     // left shift
                | ==     // equal to
                | !=     // not equal to
                | >      // greater than
                | <      // less than
                | >=     // greater than or equal to
                | <=     // less than or equal to
                | &      // bitwise AND
                | |      // bitwise OR
                | &&     // logical AND
                | ||     // logical OR
```

13.2.5. Built-in Functions

```
function_call  ::= absolute ( expr )
                | addressof ( addr_id )
                | checksum ( checksum_algo , expr , expr )
                | exists ( section_name )
                | max ( expr , expr )
                | min ( expr , expr )
                | sizeof ( size_id )

addr_id        ::= sect : section_name
                | group : group_name
                | mem : mem_name

checksum_algo  ::= crc32w

size_id        ::= sect : section_name
                | group : group_name
                | mem : mem_name
```

- Every space, bus, memory, section or group you refer to, must be defined in the LSL file.
- The `addressof()` and `sizeof()` functions with the **group** or **sect** argument can only be used in the right hand side of an assignment. The `sizeof()` function with the **mem** argument can be used anywhere in section layouts.
- The `checksum()` function can only be used in a **struct** statement.

You can use the following built-in functions in expressions. All functions return a numerical value. This value is a 64-bit signed integer.

absolute()

```
int absolute( expr )
```

Converts the value of *expr* to a positive integer.

```
absolute( "labelA"- "labelB" )
```

addressof()

```
int addressof( addr_id )
```

Returns the offset of *addr_id*, which is a named section, group, or memory in the address space of the section layout. If the referenced object is a group or memory, it must be defined in the LSL file. To get the offset of the section with the name `asect`:

```
addressof( sect: "asect" )
```

This function only works in assignments and `struct` statements.

checksum()

```
int checksum( checksum_algo, expr, expr )
```

Returns the computed checksum over a contiguous address range. The first argument specifies how the checksum must be computed (see below), the second argument is an expression that represents the start address of the range, while the third argument represents the end address (exclusive). The value of the end address expression must be strictly larger than the value of the start address (i.e. the size of the checksum address range must be at least one MAU). Each address in the range must point to a valid memory location. Memory locations in the address range that are not occupied by a section are filled with zeros.

The only checksum algorithm (*checksum_algo*) currently supported is **crc32w**. This algorithm computes the checksum using a Cyclic Redundancy Check with the "CRC-32" polynomial 0xEDB88320. The input range is processed per 4-byte word. Those 4 bytes are passed to the checksum algorithm in reverse order if the target architecture is little-endian. For big-endian targets, this checksum algorithm is equal to a regular byte-wise CRC-32 implementation. Both the start address and end address values must be aligned on 4 MAUs. The behavior of this checksum algorithm is undefined when used in an address space that has a MAU size not equal to 8.

```
checksum( crc32w,
         addressof( mem:foo ),
         addressof( mem:foo ) + sizeof( mem:foo ) )
```

This function only works in `struct` statements.

exists()

```
int exists( section_name )
```

TASKING VX-toolset for MCS User Guide

The function returns 1 if the section *section_name* exists in one or more object file, 0 otherwise. If the section is not present in input object files, but generated from LSL, the result of this function is undefined.

To check whether the section `mysection` exists in one of the object files that is specified to the linker:

```
exists( "mysection" )
```

max()

```
int max( expr, expr )
```

Returns the value of the expression that has the largest value. To get the highest value of two symbols:

```
max( "sym1" , "sym2" )
```

min()

```
int min( expr, expr )
```

Returns the value of the expression that has the smallest value. To get the lowest value of two symbols:

```
min( "sym1" , "sym2" )
```

sizeof()

```
int sizeof( size_id )
```

Returns the size of the object (group, section or memory) the identifier refers to. To get the size of the section "asection":

```
sizeof( sect: "asection" )
```

The **group** and **sect** arguments only works in assignments and **struct** statements. The **mem** argument can be used anywhere in section layouts. If the referenced object is a group or memory, it must be defined in the LSL file.

13.2.6. LSL Definitions in the Linker Script File

```
description ::= <definition>*=1
```

```
definition ::= architecture_definition  
                | derivative_definition  
                | board_spec  
                | section_definition  
                | section_setup
```

- At least one *architecture_definition* must be present in the LSL file.

13.2.7. Memory and Bus Definitions

```
mem_def ::= memory mem_name <tag_attr>0|1 { <mem_descr ;>>=0 }
```

- A *mem_def* defines a memory with the *mem_name* as a unique name.

```
mem_descr ::= type = <reserved>0|1 mem_type
| mau = expr
| size = expr
| speed = number
| priority = number
| exec_priority = number
| fill <= fill_values>0|1
| write_unit = expr
| mapping
```

- A *mem_def* contains exactly one **type** statement.
- A *mem_def* contains exactly one **mau** statement (non-zero size).
- A *mem_def* contains exactly one **size** statement.
- A *mem_def* contains zero or one **priority** (or **speed**) statement (if absent, the default value is 1).
- A *mem_def* contains zero or one **exec_priority** statement.
- A *mem_def* contains zero or one **fill** statement.
- A *mem_def* contains zero or one **write_unit** statement.
- A *mem_def* contains at least one *mapping*

```
mem_type ::= rom // attrs = rx
| ram // attrs = rw
| nvr // attrs = rwx
| blockram
```

```
fill_values ::= expr
| [ expr <, expr>>=0 ]
```

```
bus_def ::= bus bus_name { <bus_descr ;>>=0 }
```

- A *bus_def* statement defines a bus with the given *bus_name* as a unique name within a core architecture.

```
bus_descr ::= mau = expr
| width = expr // bus width, nr
| // of data bits
| mapping // legal destination
// 'bus' only
```

TASKING VX-toolset for MCS User Guide

- The **mau** and **width** statements appear exactly once in a *bus_descr*. The default value for **width** is the **mau** size.
- The bus width must be an integer times the bus MAU size.
- The MAU size must be non-zero.
- A bus can only have a *mapping* on a destination bus (through **dest = bus:**).

```
mapping          ::= map <map_name>0|1 ( map_descr <, map_descr>>=0 )
map_descr        ::= dest = destination
                  | dest_dbits = range
                  | dest_offset = expr
                  | size = expr
                  | src_dbits = range
                  | src_offset = expr
                  | reserved
                  | priority = number
                  | exec_priority = number
                  | tag
```

- A *map_descr* requires at least the **size** and **dest** statements.
- A *map_descr* contains zero or one **priority** statement (if absent, the default value is 0).
- A *map_descr* contains zero or one **exec_priority** statement.
- Each *map_descr* can occur only once.
- You can define multiple mappings from a single source.
- Overlap between source ranges or destination ranges is not allowed.
- If the **src_dbits** or **dest_dbits** statement is not present, its value defaults to the **width** value if the source/destination is a bus, and to the **mau** size otherwise.
- The **reserved** statement is allowed only in mappings defined for a memory.

```
destination      ::= space : space_name
                  | bus : <proc_name |
                        core_name :>0|1 bus_name
```

- A *space_name* refers to a defined address space.
- A *proc_name* refers to a defined processor.
- A *core_name* refers to a defined core.
- A *bus_name* refers to a defined bus.
- The following mappings are allowed (source to destination)

- space => space
- space => bus
- bus => bus
- memory => bus

range ::= *expr* .. *expr*

- With address ranges, the end address is not part of the range.

13.2.8. Architecture Definition

```
architecture_definition
    ::= architecture arch_name
       <( parameter_list )>0|1
       <extends arch_name
          <( argument_list )>0|1 >0|1
       { <arch_spec>>=0 }
```

- An *architecture_definition* defines a core architecture with the given *arch_name* as a unique name.
- At least one *space_def* and at least one *bus_def* have to be present in an *architecture_definition*.
- An *architecture_definition* that uses the **extends** construct defines an architecture that inherits all elements of the architecture defined by the second *arch_name*. The parent architecture must be defined in the LSL file as well.

parameter_list ::= *parameter* <, *parameter*>^{>=0}

parameter ::= IDENTIFIER <= *expr*>^{0|1}

argument_list ::= *expr* <, *expr*>^{>=0}

```
arch_spec ::= bus_def
              | space_def
              | endianness_def
```

space_def ::= **space** *space_name* <*tag_attr*>^{0|1} { <*space_descr*; >^{>=0} }

- A *space_def* defines an address space with the given *space_name* as a unique name within an architecture.

```
space_descr ::= space_property ;
                | section_definition //no space ref
                | vector_table_statement
                | reserved_range
```

```
space_property ::= id = number // as used in object
                  | mau = expr
```

```

| align = expr
| page_size = expr <[ range ] <| [ range ]>=>0|1
| page
| direction = direction
| stack_def
| heap_def
| copy_table_def
| start_address
| mapping

```

- A *space_def* contains exactly one **id** and one **mau** statement.
- A *space_def* contains at most one **align** statement.
- A *space_def* contains at most one **page_size** statement.
- A *space_def* contains at least one *mapping*.

```

stack_def ::= stack stack_name ( stack_descr
                                <, stack_descr >=>0 )

```

- A *stack_def* defines a stack with the *stack_name* as a unique name.

```

stack_descr ::= min_size = expr
              | grows = direction
              | align = expr
              | fixed
              | entry_points = entry_point_list
              | attributes
              | tag

```

```

entry_point_list ::= symbol_name
                  | [ symbol_name <, symbol_name >=>0 ]

```

- The **min_size** statement must be present.
- The **min_size** value must be 1 or greater.
- You can specify at most one **align** statement and one **grows** statement.
- Each stack definition can have one or more **entry_points** statements for stack estimation. The *symbol_name* corresponds to the caller name in the **.CALLS** directive as generated by the compiler.

```

heap_def ::= heap heap_name ( heap_descr
                              <, heap_descr >=>0 )

```

- A *heap_def* defines a heap with the *heap_name* as a unique name.

```

heap_descr ::= min_size = expr
              | grows = direction
              | align = expr
              | fixed

```

```

| attributes
| tag

```

- The **min_size** statement must be present.
- The **min_size** value must be 1 or greater.
- You can specify at most one **align** statement and one **grows** statement.

```

direction ::= low_to_high
| high_to_low

```

- If you do not specify the **grows** statement, the stack and heap grow **low-to-high**.

```

copy_table_def ::= copytable <( copy_table_descr
| copy_table_descr >*> )>*>

```

- A *space_def* contains at most one **copytable** statement.
- Exactly one copy table must be defined in one of the spaces.

```

copy_table_descr ::= align = expr
| copy_unit = expr
| dest <space_name>*> = space_name
| page
| tag

```

- The **copy_unit** is defined by the size in MAUs in which the startup code moves data.
- The **dest** statement is only required when the startup code initializes memory used by another processor that has no access to ROM.
- A *space_name* refers to a defined address space.

```

start_addr ::= start_address ( start_addr_descr
| start_addr_descr >*> )

```

```

start_addr_descr ::= run_addr = expr
| symbol = symbol_name

```

- A *symbol_name* refers to the section that contains the startup code.

```

vector_table_statement ::= vector_table section_name
( vecttab_spec <, vecttab_spec>*> )
{ <vector_def>*> }

```

```

vecttab_spec ::= vector_size = expr
| size = expr
| id_symbol_prefix = symbol_name
| run_addr = addr_absolute
| template = section_name
| template_symbol = symbol_name

```

```

| vector_prefix = section_name
| fill = vector_value
| no_inline
| copy
| tag

vector_def ::= vector ( vector_spec <, vector_spec>>=0 );

vector_spec ::= id = vector_id_spec
| fill = vector_value
| optional
| tag

vector_id_spec ::= number
| [ range ] <, [ range ]>>=0

vector_value ::= symbol_name
| [ number <, number>>=0 ]
| loop <[ expr ]>0|1

reserved_range ::= reserved <tag_attr>0|1 expr .. expr ;

```

- The end address is not part of the range.

```

endianness_def ::= endianness { <endianness_type; >>=1 }

endianness_type ::= big
| little

```

13.2.9. Derivative Definition

```

derivative_definition ::= derivative derivative_name
<( parameter_list )>0|1
<extends derivative_name
<( argument_list )>0|1 >0|1
{ <derivative_spec>>=0 }

```

- A *derivative_definition* defines a derivative with the given *derivative_name* as a unique name.

```

derivative_spec ::= core_def
| bus_def
| mem_def
| section_definition // no processor name
| section_setup

```

```

core_def ::= core core_name { <core_descr ; >>=0 }

```

- A *core_def* defines a core with the given *core_name* as a unique name.
- At least one *core_def* must be present in a *derivative_definition*.

```

core_def      ::= architecture = arch_name
                <( argument_list )>0|1
                | copytable_space <core_name :>0|1 space_name
                | endianness = ( endianness_type
                                <, endianness_type>>=0 )
                | import core_name
                | space_id_offset = number

```

- An *arch_name* refers to a defined core architecture.
- Exactly one **architecture** statement must be present in a *core_def*.
- Exactly one **copytable_space** statement must be present in a *core_def*, or in exactly one space in that core, a **copytable** statement must be present.

13.2.10. Processor Definition and Board Specification

```

board_spec    ::= proc_def
                | bus_def
                | mem_def

proc_def      ::= processor proc_name
                { proc_descr ; }

proc_descr    ::= derivative = derivative_name
                <( argument_list )>0|1

```

- A *proc_def* defines a processor with the *proc_name* as a unique name.
- If you do not explicitly define a processor for a derivative in an LSL file, the linker defines a processor with the same name as that derivative.
- A *derivative_name* refers to a defined derivative.
- A *proc_def* contains exactly one **derivative** statement.

13.2.11. Section Setup

```

section_setup ::= section_setup space_ref <tag_attr>0|1
                { <section_setup_item>>=0 }

section_setup_item
                ::= vector_table_statement
                | reserved_range
                | stack_def ;
                | heap_def ;
                | copy_table_def ;
                | start_address ;
                | section_reference_restriction

```

```
section_reference_restriction
    ::= section_reference_restriction
       { <section_reference_restriction_item ; >>=0 }
```

```
section_reference_restriction_item
    ::= safety_class = number
       | target_safety_class = number
       | attributes = < <attribute>>0 | - >
```

- Each *section_reference_restriction_item* can occur at most once in a **section_reference_restriction** statement.

13.2.12. Section Layout Definition

```
section_definition ::= section_layout <space_ref>0|1
                    <( space_layout_properties )>0|1
                    { <section_statement>>=0 }
```

- A section definition inside a space definition does not have a *space_ref*.
- All global section definitions have a *space_ref*.

```
space_ref          ::= <proc_name>0|1 : <core_name>0|1
                    : space_name < | space_name>>=0
```

- If more than one processor is present, the *proc_name* must be given for a global section layout.
- If the section layout refers to a processor that has more than one core, the *core_name* must be given in the *space_ref*.
- A *proc_name* refers to a defined processor.
- A *core_name* refers to a defined core.
- A *space_name* refers to a defined address space.

```
space_layout_properties
    ::= space_layout_property <, space_layout_property >>=0
```

```
space_layout_property
    ::= locate_direction
       | tag
```

```
locate_direction ::= direction = direction
```

```
direction        ::= low_to_high
                   | high_to_low
```

- A section layout contains at most one **direction** statement.
- If you do not specify the **direction** statement, the locate direction of the section layout is **low-to-high**.

```

section_statement
    ::= simple_section_statement ;
       | aggregate_section_statement

simple_section_statement
    ::= assignment
       | select_section_statement
       | special_section_statement
       | memcopy_statement

assignment      ::= symbol_name assign_op expr
assign_op       ::= =
                 | :=

select_section_statement
    ::= select <ref_tree>0|1 <section_name>0|1
       <section_selections>0|1

```

- Either a *section_name* or at least one *section_selection* must be defined.

```

section_selections
    ::= ( section_selection
         <, section_selection>>=0 )

section_selection
    ::= attributes = < <+|-> attribute>>0
       | tag

```

- **+attribute** means: select all sections that have this attribute.
- **-attribute** means: select all sections that do not have this attribute.

```

special_section_statement
    ::= heap heap_name <stack_heap_mods>0|1
       | stack stack_name <stack_heap_mods>0|1
       | copytable
       | reserved section_name <reserved_specs>0|1

```

- Special sections cannot be selected in load-time groups.

```

stack_heap_mods    ::= ( stack_heap_mod <, stack_heap_mod>>=0 )

stack_heap_mod     ::= size = expr
                   | tag

reserved_specs     ::= ( reserved_spec <, reserved_spec>>=0 )

reserved_spec      ::= attributes
                   | fill_spec
                   | size = expr
                   | alloc_allowed = absolute | ranged

```

TASKING VX-toolset for MCS User Guide

- If a **reserved** section has attributes **r**, **rw**, **x**, **rx** or **rwX**, and no fill pattern is defined, the section is filled with zeros. If no attributes are set, the section is created as a scratch section (attributes **ws**, no image).

```
memcpy_statement ::= memcpy section_name  
                  ( memcpy_spec <, memcpy_spec>0|1 )
```

```
memcpy_spec ::= memory = memory_reference  
               | fill_spec
```

- A **memcpy** statement must contain exactly one **memory** statement.
- A **memcpy** statement can contain at most one *fill_spec*.

```
fill_spec ::= fill = fill_values
```

```
fill_values ::= expr  
             | [ expr <, expr>>=0 ]
```

```
aggregate_section_statement  
 ::= { <section_statement>>=0 }  
     | group_descr  
     | if_statement  
     | section_creation_statement  
     | struct_statement
```

```
group_descr ::= group <group_name>0|1 <( group_specs )>0|1  
              section_statement
```

- For every group with a name, the linker defines a label.
- No two groups for address spaces of a core can have the same *group_name*.

```
group_specs ::= group_spec <, group_spec >>=0
```

```
group_spec ::= group_alignment  
              | attributes  
              | copy  
              | nocopy  
              | group_load_address  
              | fill <= fill_values>0|1  
              | group_page  
              | group_run_address  
              | group_type  
              | allow_cross_references  
              | priority = number  
              | group_safety_class  
              | tag
```

- The **allow-cross-references** property is only allowed for *overlay* groups.

- The `copy` and `nocopy` properties cannot be applied both to the same group.
- Sub groups inherit all properties from a parent group.

```

group_alignment ::= align = expr

attributes      ::= attributes = <attribute>*>=1

attribute       ::= r    // readable sections
                  | w    // writable sections
                  | x    // executable code sections
                  | i    // initialized sections
                  | s    // scratch sections
                  | b    // blanked (cleared) sections
                  | p    // protected sections

group_load_address ::= load_addr <= load_or_run_addr>^0|1

group_page       ::= page <= expr>^0|1
                  | page_size = expr <[ range ] <| [ range ]>*>=0^0|1

group_run_address ::= run_addr <= load_or_run_addr>^0|1

group_type       ::= clustered
                  | contiguous
                  | ordered
                  | overlay
    
```

- For *non-contiguous* groups, you can only specify `group_alignment` and `attributes`.
- The `overlay` keyword also sets the `contiguous` property.
- The `clustered` property cannot be set together with `contiguous` or `ordered` on a single group.

```

group_safety_class ::= safety_class = number

load_or_run_addr  ::= addr_absolute
                  | addr_range <| addr_range>*>=0

addr_absolute     ::= expr
                  | memory_reference [ expr ]
    
```

- An absolute address can only be set on *ordered* groups.

```

addr_range        ::= [ expr .. expr ]
                  | memory_reference
                  | memory_reference [ expr .. expr ]
    
```

- The parent of a group with an `addr_range` or `page` restriction cannot be `ordered`, `contiguous` or `clustered`.

TASKING VX-toolset for MCS User Guide

- The end address is not part of the range.

```
memory_reference ::= mem : <proc_name :>0|1 mem_name </ map_name>0|1
```

- A *proc_name* refers to a defined processor.
- A *mem_name* refers to a defined memory.
- A *map_name* refers to a defined memory mapping.

```
if_statement ::= if ( expr ) section_statement  
              <else section_statement>0|1
```

```
section_creation_statement  
    ::= section section_name ( section_specs )  
       { <section_statement2>>=0 }
```

```
section_specs ::= section_spec <, section_spec >>=0
```

```
section_spec ::= attributes  
              | fill_spec  
              | size = expr  
              | blocksize = expr  
              | overflow = section_name  
              | tag
```

```
section_statement2  
    ::= select_section_statement ;  
       | group_descr2  
       | { <section_statement2>>=0 }
```

```
group_descr2 ::= group <group_name>0|1  
              ( group_specs2 )  
              section_statement2
```

```
group_specs2 ::= group_spec2 <, group_spec2 >>=0
```

```
group_spec2 ::= group_alignment  
             | attributes  
             | load_addr  
             | nocopy  
             | tag
```

```
struct_statement  
    ::= struct { <struct_item>>=0 }
```

```
struct_item ::= expr : number ;
```

13.3. Expression Evaluation

Only *constant* expressions are allowed, including sizes, but not addresses, of sections in object files.

All expressions are evaluated with 64-bit precision integer arithmetic. The result of an expression can be absolute or relocatable. A symbol you assign is created as an absolute symbol. Symbol references are only allowed in symbol assignments and `struct` statements.

13.4. Semantics of the Architecture Definition

Keywords in the architecture definition

```

architecture
  extends
endianness          big  little
bus
  mau
  width
  map
space
  id
  mau
  align
  page_size

    id
    fill      loop
    optional
reserved
start_address
    run_addr
    symbol
map

map
    dest      bus space
    dest_dbits
    dest_offset
    size
    src_dbits
    src_offset
    priority
    exec_priority
```

13.4.1. Defining an Architecture

With the keyword **architecture** you define an architecture and assign a unique name to it. The name is used to refer to it at other places in the LSL file:

```
architecture name
{
    definitions
}
```

If you are defining multiple core architectures that show great resemblance, you can define the common features in a parent core architecture and extend this with a child core architecture that contains specific features. The child inherits all features of the parent. With the keyword **extends** you create a child core architecture:

```
architecture name_child_arch extends name_parent_arch
{
    definitions
}
```

A core architecture can have any number of parameters. These are identifiers which get values assigned on instantiation or extension of the architecture. You can use them in any expression within the core architecture. Parameters can have default values, which are used when the core architecture is instantiated with less arguments than there are parameters defined for it. When you extend a core architecture you can pass arguments to the parent architecture. Arguments are expressions that set the value of the parameters of the sub-architecture.

```
architecture name_child_arch (parm1,parm2=1)
    extends name_parent_arch (arguments)
```

```
{
    definitions
}
```

13.4.2. Defining Internal Buses

With the **bus** keyword you define a bus (the combination of data and corresponding address bus). The bus name is used to identify a bus and does not conflict with other identifiers. Bus descriptions in an architecture definition or derivative definition define *internal* buses. Some internal buses are used to communicate with the components outside the core or processor. Such buses on a processor have physical pins reserved for the number of bits specified with the **width** statements.

- The **mau** field specifies the MAU size (Minimum Addressable Unit) of the data bus. This field is required and must be non-zero.
- The **width** field specifies the width (number of address lines) of the data bus. The default value is the MAU size.
- The **map** keyword specifies how this bus maps onto another bus (if so). Mappings are described in [Section 13.4.4, *Mappings*](#).

```
bus bus_name
{
    mau = 8;
    width = 8;
    map ( map_description );
}
```

13.4.3. Defining Address Spaces

With the **space** keyword you define a logical address space. The space name is used to identify the address space and does not conflict with other identifiers.

- The **id** field defines how the addressing space is identified in object files. In general, each address space has a unique ID. The linker locates sections with a certain ID in the address space with the same ID. This field is required.
- The **mau** field specifies the MAU size (Minimum Addressable Unit) of the space. This field is required and must be non-zero.
- The **align** value must be a power of two. The linker uses this value to compute the start addresses when sections are concatenated. An align value of *n* means that objects in the address space have to be aligned on *n* MAUs.
- The **page_size** field sets the page alignment and page size in MAUs for the address space. It must be a power of 2. The default value is 1. If one or more page ranges are supplied the supplied value only sets the page alignment. The ranges specify the available space in each page, as offsets to the page start, which is aligned at the page alignment.

See also the **page** keyword in subsection [Locating a group](#) in [Section 13.8.2, *Creating and Locating Groups of Sections*](#).

TASKING VX-toolset for MCS User Guide

- With the optional **direction** field you can specify how all sections in this space should be located. This can be either from **low_to_high** addresses (this is the default) or from **high_to_low** addresses.
- The **map** keyword specifies how this address space maps onto an internal bus or onto another address space. Mappings are described in [Section 13.4.4, *Mappings*](#).

Stacks and heaps

- The **stack** keyword defines a stack in the address space and assigns a name to it. The architecture definition must contain at least one stack definition. Each stack of a core architecture must have a unique name. See also the **stack** keyword in [Section 13.8.3, *Creating or Modifying Special Sections*](#).

The stack is described in terms of a minimum size (**min_size**) and the direction in which the stack grows (**grows**). This can be either from **low_to_high** addresses (stack grows upwards, this is the default) or from **high_to_low** addresses (stack grows downwards). The **min_size** is required.

By default, the linker tries to maximize the size of the stacks and heaps. After locating all sections, the largest remaining gap in the space is used completely for the stacks and heaps. If you specify the keyword **fixed**, you can disable this so-called 'balloon behavior'. The size is also fixed if you used a stack or heap in the software layout definition in a restricted way. For example when you override a stack with another size or select a stack in an ordered group with other sections.

A stack may have an **attributes** property with value **b**. Such a stack must be cleared at program startup. No other attributes are allowed.

Optionally you can specify an alignment for the stack with the argument **align**. This alignment must be equal or larger than the alignment that you specify for the address space itself.

For each stack, a stack size estimation may be computed (and listed in a map file) from a call graph. Each root node of the call graph is treated as a separate thread that can run independently from the other threads. Root nodes can be specified using the **entry_points** keyword. The estimated stack usage for a root node is the highest sum of stack usage values along a path to a leaf node. The total estimated stack usage of a link task is the sum of the calculated stack usage of such independent call graphs.

A stack definition may have one or more **entry_points** statements that specify the code that uses that stack - all functions that are reachable (by calls) from the entry points are considered to be using the stack at run-time. Each symbol name specified as an entry point must match a node in the call graph, which must not have more than one caller. As a result of the entry point specification, the specific call (edge) is removed from the call graph (so the symbol becomes a root). A symbol may be declared as entry point for multiple stacks.

In the LSL file the value of the **entry_points** argument can be determined by the macro `GTM_MCScore_STACK_n_ENTRY_POINTS` for each channel *n* for MCS core *core*. By default the macro for the main channel is set to `"__START"`.

- The **heap** keyword defines a heap in the address space and assigns a name to it. The definition of a heap is similar to the definition of a stack. See also the **heap** keyword in [Section 13.8.3, *Creating or Modifying Special Sections*](#).

Stacks and heaps are only generated by the linker if the corresponding linker labels are referenced in the object files.

See [Section 13.8, Semantics of the Section Layout Definition](#), for information on creating and placing stack sections.

Copy tables

- The `copytable` keyword defines a copy table in the address space. The content of the copy table is created by the linker and contains the start address and size of all sections that should be initialized by the startup code. You must define exactly one copy table in one of the address spaces (for a core).

Optionally you can specify an alignment for the copy table with the argument `align`. This alignment must be equal or larger than the alignment that you specify for the address space itself. If smaller, the alignment for the address space is used.

The `copy_unit` argument specifies the size in MAUs of information chunks that are copied. If you do not specify the copy unit, the MAU size of the address space itself is used.

The `dest` argument specifies the destination address space that the code uses for the copy table. The linker uses this information to generate the correct addresses in the copy table. The memory into where the sections must be copied at run-time, must be accessible from this destination space.

Sections generated for the copy table may get a page restriction with the address space's page size, by adding the `page` argument.

Vector table

- The `vector_table` keyword defines a vector table with n vectors of size m (This is an internal LSL object similar to an LSL group.) The `run_addr` argument specifies the location of the first vector (`id=0`). This can be a simple address or an offset in memory (see the description of the run-time address in subsection [Locating a group](#) in [Section 13.8.2, Creating and Locating Groups of Sections](#)). A vector table defines symbols `_lc_ub_foo` and `_lc_ue_foo` pointing to start and end of the table.

```
vector_table "vector_table" (vector_size=m, size=n, run_addr=x, ...)
```

See the following example of a vector table definition:

```
vector_table "vector_table" (vector_size = 4, size = 8, run_addr=0,
                             template=".mcstext.vector",
                             template_symbol="_lc_vector_target",
                             vector_prefix=".vector.",
                             id_symbol_prefix="foo",
                             no_inline,
                             /* default: empty, or */
                             fill="foo", /* or */
                             fill=[1,2,3,4], /* or */
                             fill=loop)
{
    vector (id=0, fill="__START");
    vector (id=23, fill="main", optional);
    vector (id=12, fill=[0xab, 0x21, 0x32, 0x43]);
    vector (id=[1..11], fill=[0]);
}
```

```
    vector (id=[18..23], fill=loop);  
}
```

The **template** argument defines the name of the section that holds the code to jump to a handler function from the vector table. This template section does not get located and is removed when the locate phase is completed. This argument is required.

The **template_symbol** argument is the symbol reference in the template section that must be replaced by the address of the handler function. This symbol name should start with the linker prefix for the symbol to be ignored in the link phase. This argument is required.

The **vector_prefix** argument defines the names of vector sections: the section for a vector with id *vector_id* is $\$(vector_prefix)\$(vector_id)$. Vectors defined in C or assembly source files that should be included in the vector table must have the correct symbol name. The compiler uses the prefix that is defined in the default LSL file(s); if this attribute is changed, the vectors declared in C source files are not included in the vector table. When a vector supplied in an object file has exactly one relocation, the linker will assume it is a branch to a handler function, and can be removed when the handler is inlined in the vector table. Otherwise, no inlining is done. This argument is required.

With the optional **no_inline** argument the vectors handlers are not inlined in the vector table.

With the optional **copy** argument a ROM copy of the vector table is made and the vector table is copied to RAM at startup.

With the optional **id_symbol_prefix** argument you can set an internal string representing a symbol name prefix that may be found on symbols in vector handler code. When the linker detects such a symbol in a handler, the symbol is assigned the vector number. If the symbol was already assigned a vector number, a warning is issued.

The **fill** argument sets the default contents of vectors. If nothing is specified for a vector, this setting is used. See below. When no default is provided, empty vectors may be used to locate large vector handlers and other sections. Only one **fill** argument is allowed.

The **vector** field defines the content of vector with the number specified by **id**. If a range is specified for **id** ($[p..q, s..t]$) all vectors in the ranges (inclusive) are defined the same way.

With **fill=symbol_name**, the vector must jump to this symbol. If the section in which the symbol is defined fits in the vector table (size may be $>m$), locate the section at the location of the vector. Otherwise, insert code to jump to the symbol's value. A template interrupt handler section name + symbol name for the target code must be supplied in the LSL file.

fill=[value(s)], fills the vector with the specified MAU values.

With **fill=loop** the vector jumps to itself. With the optional **[offset]** you can specify an offset from the vector table entry.

When the keyword **optional** is set on a vector specification with a symbol value and the symbol is not found, no error is reported. A default fill value is used if the symbol was not found. With other values the attribute has no effect.

Reserved address ranges

- The **reserved** keyword specifies to reserve a part of an address space even if not all of the range is covered by memory. See also the **reserved** keyword in [Section 13.8.3, *Creating or Modifying Special Sections*](#).

Start address

- The **start_address** keyword specifies the start address for the position where the startup code is located. When a processor is reset, it initializes its program counter to a certain start address, sometimes called the reset vector. In the architecture definition, you must specify this start address in the correct address space in combination with the name of the label in the application code which must be located here.

The **run_addr** argument specifies the start address (reset vector). If the core starts executing using an entry from a vector table, and directly jumps to the start label, you should omit this argument.

The **symbol** argument specifies the name of the label in the application code that should be located at the specified start address. The **symbol** argument is required. The linker will resolve the start symbol and use its value after locating for the start address field in IEEE-695 files and Intel Hex files. If you also specified the **run_addr** argument, the start symbol (label) must point to a section. The linker locates this section such that the start symbol ends up on the start address.

```
space space_name
{
    id = 1;
    mau = 8;
    align = 8;
    page_size = 1;
    stack name (min_size = 1k, grows = low_to_high);
    reserved start_address .. end_address;
    start_address ( run_addr = 0x0000,
                  symbol = "start_label" )
    map ( map_description );
}
```

13.4.4. Mappings

You can use a mapping when you define a space, bus or memory. With the **map** field you specify how addresses from the source (space, bus or memory) are translated to addresses of a destination (space, bus). The following mappings are possible:

- space => space
- space => bus
- bus => bus
- memory => bus

TASKING VX-toolset for MCS User Guide

With a mapping you specify a range of source addresses you want to map (specified by a source offset and a size), the destination to which you want to map them (a bus or another address space), and the offset address in the destination.

- The **dest** argument specifies the destination. This can be a **bus** or another address **space** (only for a space to space mapping). This argument is required.
- The **src_offset** argument specifies the offset of the source addresses. In combination with size, this specifies the range of address that are mapped. By default the source offset is 0x0000.
- The **size** argument specifies the number of addresses that are mapped. This argument is required.
- The **dest_offset** argument specifies the position in the destination to which the specified range of addresses is mapped. By default the destination offset is 0x0000.

If you are mapping a bus to another bus, the number of data lines of each bus may differ. In this case you have to specify a range of source data lines you want to map (**src_dbits = begin..end**) and the range of destination data lines you want to map them to (**dest_dbits = first..last**).

- The **src_dbits** argument specifies a range of data lines of the source bus. By default all data lines are mapped.
- The **dest_dbits** argument specifies a range of data lines of the destination bus. By default, all data lines from the source bus are mapped on the data lines of the destination bus (starting with line 0).

A mapping can optionally have a name which can be referenced in an address assignment.

If you define a memory and the memory mapping must not be used by default when locating sections in address spaces, you can specify the **reserved** argument. This marks all address space areas that the mapping points to as reserved. If a section has an absolute or address range restriction, the reservation is lifted and the section may be located at these locations. This feature is only useful when more than one mapping is available for a range of memory addresses, otherwise the **memory** keyword with the same name would be used.

For example:

```
memory xrom
{
    mau = 8;
    size = 1M;
    type = rom;
    map    cached (dest=bus:spe:fpi_bus, dest_offset=0x80000000,
                  size=1M);
    map    not_cached (dest=bus:spe:fpi_bus, dest_offset=0xa0000000,
                      size=1M, reserved);
}
```

Mapping priority

If you define a memory you can set a locate priority on a mapping with the keywords **priority** and **exec_priority**. The values of these priorities are relative which means they add to the priority of memories. Whereas a priority set on the memory applies to all address space areas reachable through

any mapping of the memory, a priority set on a mapping only applies to address space areas reachable through the mapping. The memory mapping with the highest priority is considered first when locating. To set only a priority for non-executable (data) sections, add a `priority` keyword with the desired value and an `exec_priority` set to zero. To set only a priority for executable (code) sections, simply set an `exec_priority` keyword to the desired value.

The default for a mapping `priority` is zero, while the default for `exec_priority` is the same as the specified `priority`. If you specify a value for `priority` in LSL it must be greater than zero. A value for `exec_priority` must be greater or equal to zero.

For more information about priority values see the description of the [memory priority keyword](#).

```
memory dspram
{
    mau = 8;
    size = 112k;
    type = ram;
    map (dest=bus:mycore_1:fpi_bus, dest_offset=0xd0000000,
        size=112k, priority=8, exec_priority=0);
    map (dest=bus:sri, dest_offset=0x70000000,
        size=112k);
}
```

From space to space

If you map an address space to another address space (nesting), you can do this by mapping the subspace to the containing larger space. In this example a small space of 64 kB is mapped on a large space of 16 MB.

```
space small
{
    id = 2;
    mau = 4;
    map (src_offset = 0, dest_offset = 0,
        dest = space : large, size = 64k);
}
```

From space to bus

All spaces that are not mapped to another space must map to a bus in the architecture:

```
space large
{
    id = 1;
    mau = 4;
    map (src_offset = 0, dest_offset = 0,
        dest = bus:bus_name, size = 16M );
}
```

From bus to bus

The next example maps an external bus called `e_bus` to an internal bus called `i_bus`. This internal bus resides on a core called `mycore`. The source bus has 16 data lines whereas the destination bus has only 8 data lines. Therefore, the keywords `src_dbits` and `dest_dbits` specify which source data lines are mapped on which destination data lines.

```
architecture mycore
{
    bus i_bus
    {
        mau = 4;
    }

    space i_space
    {
        map (dest=bus:i_bus, size=256);
    }
}

bus e_bus
{
    mau = 16;
    width = 16;
    map (dest = bus:mycore:i_bus, src_dbits = 0..7, dest_dbits = 0..7 )
}
```

It is not possible to map an internal bus to an external bus.

13.5. Semantics of the Derivative Definition

Keywords in the derivative definition

```
derivative
    extends
core
    architecture
    import
    space_id_offset
    copytable_space
bus
    mau
    width
    map
memory
    type          reserved rom ram nvrAm blockram
    mau
    size
```

```

speed
priority
exec_priority
fill
write_unit
map
section_layout
section_setup

map
    dest          bus space
    dest_dbits
    dest_offset
    size
    src_dbits
    src_offset
    priority
    exec_priority
    reserved

```

13.5.1. Defining a Derivative

With the keyword **derivative** you define a derivative and assign a unique name to it. The name is used to refer to it at other places in the LSL file:

```

derivative name
{
    definitions
}

```

If you are defining multiple derivatives that show great resemblance, you can define the common features in a parent derivative and extend this with a child derivative that contains specific features. The child inherits all features of the parent (cores and memories). With the keyword **extends** you create a child derivative:

```

derivative name_child_deriv extends name_parent_deriv
{
    definitions
}

```

As with a core architecture, a derivative can have any number of parameters. These are identifiers which get values assigned on instantiation or extension of the derivative. You can use them in any expression within the derivative definition.

```

derivative name_child_deriv (parm1,parm2=1)
    extends name_parent_deriv (arguments)
{
    definitions
}

```

13.5.2. Instantiating Core Architectures

With the keyword `core` you instantiate a core architecture in a derivative.

- With the keyword `architecture` you tell the linker that the given core has a certain architecture. The architecture name refers to an existing architecture definition in the same LSL file.

For example, if you have two cores (called `mycore_1` and `mycore_2`) that have the same architecture (called `mycorearch`), you must instantiate both cores as follows:

```
core mycore_1
{
    architecture = mycorearch;
}

core mycore_2
{
    architecture = mycorearch;
}
```

If the architecture definition has parameters you must specify the arguments that correspond with the parameters. For example `mycorearch1` expects two parameters which are used in the architecture definition:

```
core mycore
{
    architecture = mycorearch1 (1,2);
}
```

- With the keyword `import` you can combine multiple cores with the same architecture into a single link task. The imported cores share a single symbol namespace.
- The address spaces in each imported core must have a unique ID in the link task. With the keyword `space_id_offset` you specify for each imported core that the space IDs of the imported core start at a specific offset.
- With the keyword `copytable_space` you can specify that writable sections for a core must be initialized by using the copy table of a different core.

```
core mycore_1
{
    architecture = mycorearch;
    space_id_offset = 100; // add 100 to all space IDs in
                          // the architecture definition
    copytable_space = mycore:myspace; // use copytable from core mycore
}
core mycore_2
{
    architecture = mycorearch;
    space_id_offset = 200; // add 200 to all space IDs in
                          // the architecture definition
}
```

```

    copytable_space = mycore:myspace; // use copytable from core mycore
}

core mycore
{
    architecture = mycorearch;
    import mycore_1; // add all address spaces of mycore_1 for linking
    import mycore_2; // add all address spaces of mycore_2 for linking
}

```

13.5.3. Defining Internal Memory and Buses

With the keyword **memory** you define physical memory that is present on the target board. The memory name is used to identify the memory and does not conflict with other identifiers. It is common to define internal memory (on-chip) in the derivative definition. External memory (off-chip memory) is usually defined in the board specification (See [Section 13.6.3, *Defining External Memory and Buses*](#)).

- The **type** field specifies a memory type:
 - **rom**: read-only memory - it can only be written at load-time
 - **ram**: random access volatile writable memory - writing at run-time is possible while writing at load-time has no use since the data is not retained after a power-down
 - **nvr****am**: non volatile ram - writing is possible both at load-time and run-time
 - **blockram**: writing is possible both at load-time and run-time. Changes are applied in RAM, so after a full device reset the data in a blockram reverts to the original state.

The optional **reserved** qualifier before the memory type, tells the linker not to locate any section in the memory by default. You can locate sections in such memories using an absolute address or range restriction (see subsection [Locating a group](#) in [Section 13.8.2, *Creating and Locating Groups of Sections*](#)).

- The **mau** field specifies the MAU size (Minimum Addressable Unit) of the memory. This field is required and must be non-zero.
- The **size** field specifies the size in MAU of the memory. This field is required.
- The **priority** field specifies a locate priority for a memory. The **speed** field has the same meaning but is considered deprecated. By default, a memory has its priority set to 1. The memories with the highest priority are considered first when trying to locate a rule. Subsequently, the next highest priority memories are added if the rule was not located successfully, and so on until the lowest priority that is available is reached or the rule is located. The lowest priority value is zero. Sections with an **ordered** and/or **contiguous** restriction are not affected by the locate priority. If such sections also have a **page** restriction, the locate priority is still used to select a page.
- If an **exec_priority** is specified for a memory, the regular priority (either specified or its default value) does not apply to locate rules with only executable sections. Instead, the supplied value applies for such rules. Additionally, the **exec_priority** value is used for any executable unrestricted sections, even if they appear in an unrestricted rule together with non-executable sections.

- The **map** field specifies how this memory maps onto an (internal) bus. The mapping can have a name. Mappings are described in [Section 13.4.4, Mappings](#).
- The optional **write_unit** field specifies the minimum write unit (MWU). This is the minimum number of MAUs required in a write action. This is useful to initialize memories that can only be written in units of two or more MAUs. If **write_unit** is not defined the minimum write unit is 0.
- The optional **fill** field contains a bit pattern that the linker writes to all memory addresses that remain unoccupied during the locate process. The result of the expression, or list of expressions, is used as values to write to memory, each in MAU.

```
memory mem_name
{
    type = rom;
    mau = 8;
    write_unit = 4;
    fill = 0xaa;
    size = 64k;
    priority = 2;
    map map_name ( map_description );
}
```

With the **bus** keyword you define a bus in a derivative definition. Buses are described in [Section 13.4.2, Defining Internal Buses](#).

13.6. Semantics of the Board Specification

Keywords in the board specification

```
processor
    derivative
bus
    mau
    width
    map
memory
    type          reserved rom ram nvram blockram
    mau
    size
    speed
    priority
    exec_priority
    fill
    write_unit
    map

    map
        dest          bus space
        dest_dbits
```

```

dest_offset
size
src_dbits
src_offset
priority
exec_priority
reserved

```

13.6.1. Defining a Processor

If you have a target board with multiple processors that have the same derivative, you need to instantiate each individual processor in a processor definition. This information tells the linker which processor has which derivative and enables the linker to distinguish between the present processors.

If you use processors that all have a unique derivative, you may omit the processor definitions. In this case the linker assumes that for each derivative definition in the LSL file there is one processor. The linker uses the derivative name also for the processor.

With the keyword **processor** you define a processor. You can freely choose the processor name. The name is used to refer to it at other places in the LSL file:

```

processor proc_name
{
    processor definition
}

```

13.6.2. Instantiating Derivatives

With the keyword **derivative** you tell the linker that the given processor has a certain derivative. The derivative name refers to an existing derivative definition in the same LSL file.

For example, if you have two processors on your target board (called `myproc_1` and `myproc_2`) that have the same derivative (called `myderiv`), you must instantiate both processors as follows:

```

processor myproc_1
{
    derivative = myderiv;
}

processor myproc_2
{
    derivative = myderiv;
}

```

If the derivative definition has parameters you must specify the arguments that correspond with the parameters. For example `myderiv1` expects two parameters which are used in the derivative definition:

```

processor myproc
{

```

```
    derivative = myderiv1 (2,4);  
}
```

13.6.3. Defining External Memory and Buses

It is common to define external memory (off-chip) and external buses at the global scope (outside any enclosing definition). Internal memory (on-chip memory) is usually defined in the scope of a derivative definition.

With the keyword **memory** you define physical memory that is present on the target board. The memory name is used to identify the memory and does not conflict with other identifiers. If you define memory parts in the LSL file, only the memory defined in these parts is used for placing sections.

If no external memory is defined in the LSL file and if the linker option to allocate memory on demand is set then the linker will assume that all virtual addresses are mapped on physical memory. You can override this behavior by specifying one or more memory definitions.

```
memory mem_name  
{  
    type = rom;  
    mau = 8;  
    write_unit = 4;  
    fill = 0xaa;  
    size = 64k;  
    priority = 2;  
    map map_name ( map_description );  
}
```

For a description of the keywords, see [Section 13.5.3, Defining Internal Memory and Buses](#).

With the keyword **bus** you define a bus (the combination of data and corresponding address bus). The bus name is used to identify a bus and does not conflict with other identifiers. Bus descriptions at the global scope (outside any definition) define external buses. These are buses that are present on the target board.

```
bus bus_name  
{  
    mau = 8;  
    width = 8;  
    map ( map_description );  
}
```

For a description of the keywords, see [Section 13.4.2, Defining Internal Buses](#).

You can connect off-chip memory to any derivative: you need to map the off-chip memory to a bus and map that bus on the internal bus of the derivative you want to connect it to.

13.7. Semantics of the Section Setup Definition

Keywords in the section setup definition

```

section_setup
  stack
    min_size
    grows          low_to_high  high_to_low
    align
    fixed
    id
  heap
    min_size
    grows          low_to_high  high_to_low
    align
    fixed
    id

  copytable
    align
    copy_unit
    dest
    page
  vector_table
    vector_size
    size
    id_symbol_prefix
    run_addr
    template
    template_symbol
    vector_prefix
    fill
    no_inline
    copy
    vector
      id
      fill      loop
      optional
  reserved
  start_address
    run_addr
    symbol
  section_reference_restriction
    safety_class
    target_safety_class
    attributes

```

13.7.1. Setting up a Section

With the keyword `section_setup` you can define stacks, heaps, copy tables, vector tables, start address and/or reserved address ranges outside their address space definition. In addition you can configure section reference restrictions.

```
section_setup ::my_space
{
    vector table statements
    reserved address range
    stack definition
    heap definition
    copy table definition
    start address
    section reference restrictions
}
```

See the subsections [Stacks and heaps](#), [Copy tables](#), [Start address](#), [Vector table](#) and [Reserved address ranges](#) in [Section 13.4.3, Defining Address Spaces](#) for details on the keywords `stack`, `heap`, `copytable`, `vector_table` and `reserved`.

Section reference restrictions

With a `section_reference_restriction` statement you can specify what access operations are allowed between specific combinations of sections. Instead of selecting sections directly, the concept of a *safety class* is introduced. A safety class is associated with a collection of sections and is represented by a positive integer number. Safety classes are disjunct subsets of the set of sections that is emitted in absolute output object files. Initially, all sections are in safety class 0. By default, all access is prohibited unless the two sections are part of the same safety class. In that case, all access is allowed.

For example,

```
#define SC_ASIL_A 3
section_setup :mcs00:mcs
{
    section_reference_restriction
    {
        safety_class = SC_ASIL_A;
        target_safety_class = 7;
        attributes = r;
        // safety class '3' only has read access in safety class '7'
    }
}
```

13.8. Semantics of the Section Layout Definition

Keywords in the section layout definition

```

section_layout
  direction      low_to_high  high_to_low
group
  align
  attributes     + - r w x b i s p
  copy
  nocopy
  fill
  ordered
  contiguous
  clustered
  overlay
  allow_cross_references
  load_addr
    mem
  run_addr
    mem
  page
  page_size
  priority
  safety_class
select
stack
  size
heap
  size
reserved
  size
  attributes     r w x
  fill
  alloc_allowed absolute ranged
copytable
memcpy
  memory
  fill
section
  size
  blocksize
  attributes     r w x
  fill
  overflow
struct
  checksum

if
else

```

13.8.1. Defining a Section Layout

With the keyword `section_layout` you define a section layout for exactly one address space. In the section layout you can specify how input sections are placed in the address space, relative to each other, and what the absolute run and load addresses of each section will be.

You can define one or more section definitions. Each section definition arranges the sections in one address space. You can precede the address space name with a processor name and/or core name, separated by colons. You can omit the processor name and/or the core name if only one processor is defined and/or only one core is present in the processor. A reference to a space in the only core of the only processor in the system would look like " : :my_space". A reference to a space of the only core on a specific processor in the system could be "my_chip : :my_space". The next example shows a section definition for sections in the `my_space` address space of the processor called `my_chip`:

```
section_layout my_chip::my_space ( locate_direction )
{
    section statements
}
```

Locate direction

With the optional keyword `direction` you specify whether the linker starts locating sections from `low_to_high` (default) or from `high_to_low`. In the second case the linker starts locating sections at the highest addresses in the address space but preserves the order of sections when necessary (one processor and core in this example).

```
section_layout ::my_space ( direction = high_to_low )
{
    section statements
}
```

If you do not explicitly tell the linker how to locate a section, the linker decides on the basis of the section attributes in the object file and the information in the architecture definition and memory parts where to locate the section.

13.8.2. Creating and Locating Groups of Sections

Sections are located per group. A group can contain one or more (sets of) input sections as well as other groups. Per group you can assign a mutual order to the sets of sections and locate them into a specific memory part.

```
group ( group_specifications )
{
    section_statements
}
```

With the `section_statements` you generally select sets of sections to form the group. This is described in subsection [Selecting sections for a group](#).

Instead of selecting sections, you can also modify special sections like stack and heap or create a reserved section. This is described in [Section 13.8.3, *Creating or Modifying Special Sections*](#).

With the *group_specifications* you actually locate the sections in the group. This is described in subsection [Locating a group](#).

Selecting sections for a group

With the keyword `select` you can select one or more sections for the group. You can select a section by name or by attributes. If you select a section by name, you can use a wildcard pattern:

- * matches with all section names
- ? matches with a single character in the section name
- \ takes the next character literally
- [abc] matches with a single 'a', 'b' or 'c' character
- [a-z] matches with any single character in the range 'a' to 'z'

```
group ( ... )
{
    select "mysection";
    select "*";
}
```

The first `select` statement selects the section with the name "mysection". The second `select` statement selects all sections that were not selected yet.

A section is selected by the first select statement that matches, in the union of all section layouts for the address space. Global section layouts are processed in the order in which they appear in the LSL file. Internal core architecture section layouts always take precedence over global section layouts.

When you use wildcards, the linker skips sections with an absolute address from the selection process, for example, a start section already having an absolute start address.

Note that when you select sections with an exact name (no wildcards), all sections with that name are automatically protected against unreferenced section removal. With a selection using wildcards, matching sections are selected, but matching sections that are unreferenced may be removed.

- The `attributes` field selects all sections that carry (or do not carry) the given attribute. With `+attribute` you select sections that have the specified attribute set. With `-attribute` you select sections that do not have the specified attribute set. You can specify one or more of the following attributes:
 - `r` readable sections
 - `w` writable sections
 - `x` executable sections
 - `i` initialized sections
 - `b` sections that should be cleared at program startup

TASKING VX-toolset for MCS User Guide

- **s** scratch sections (not cleared and not initialized)
- **p** protected sections

To select all read-only sections:

```
group ( ... )
{
    select (attributes = +r-w);
}
```

Keep in mind that all section selections are restricted to the address space of the section layout in which this group definition occurs.

- With the **ref_tree** field you can select a group of related sections. The relation between sections is often expressed by means of references. By selecting just the 'root' of tree, the complete tree is selected. This is for example useful to locate a group of related sections in special memory (e.g. fast memory). The (referenced) sections must meet the following conditions in order to be selected:
 1. The sections are within the section layout's address space
 2. The sections match the specified attributes
 3. The sections have no absolute restriction (as is the case for all wildcard selections)

For example, to select the code sections referenced from `foo1`:

```
group refgrp (contiguous, run_addr=mem:ext_c)
{
    select ref_tree "foo1" (attributes=+x);
}
```

If section `foo1` references `foo2` and `foo2` references `foo3`, then all these sections are selected by the selection shown above.

Locating a group

```
group group_name ( group_specifications )
{
    section_statements
}
```

With the *group_specifications* you actually define how the linker must locate the group. You can roughly define three things: 1) assign properties to the sections in a group like alignment and read/write attributes, 2) define the mutual order in the address space for sections in the group and 3) restrict the possible addresses for the sections in a group.

The linker creates labels that allow you to refer to the begin and end address of a group from within the application software. Labels `_lc_gb_group_name` and `_lc_ge_group_name` mark the begin and end of the group respectively, where the begin is the lowest address used within this group and the end is the highest address used. Notice that a group not necessarily occupies all memory between begin and end address. The given label refers to where the section is located at run-time (versus load-time).

1. Assign properties to the sections in a group like alignment and read/write attributes.

These properties are assigned to all sections in the group (and subgroups) and override the attributes of the input sections.

- The **align** field tells the linker to align all sections in the group according to the align value. The alignment of a section is first determined by its own initial alignment and the defined alignment for the address space. Alignments are never decreased, if multiple alignments apply to a section, the largest one is used.
- The **attributes** field tells the linker to assign one or more attributes to all sections in the group. This overrules the default attributes. By default the linker uses the attributes of the input sections. You can set the **r**, **w**, or **rw** attributes and you can switch between the **b** and **s** attributes.
- The **copy** field tells the linker to locate a read-only section in RAM and generate a ROM copy and a copy action in the copy table. This property makes the sections in the group writable which causes the linker to generate ROM copies for the sections.
- The effect of the **nocopy** field is the opposite of the **copy** field. It prevents the linker from generating ROM copies of the selected sections. You cannot apply both **copy** and **nocopy** to the same statement.

2. Define the mutual order of sections in an LSL group.

By default, a group is *unrestricted* which means that the linker has total freedom to place the sections of the group in the address space.

Note that when you use the linker optimization option `--optimize+=copytable-compression`, unrestricted sections affected by the copy table are located as if they were in a clustered LSL group. This option is enabled by default.

- The **ordered** keyword tells the linker to locate the sections in the same order in the address space as they appear in the group (but not necessarily adjacent).

Suppose you have an ordered group that contains the sections 'A', 'B' and 'C'. By default the linker places the sections in the address space like 'A' - 'B' - 'C', where section 'A' gets the lowest possible address. With `direction=high_to_low` in the `section_layout` space properties, the linker places the sections in the address space like 'C' - 'B' - 'A', where section 'A' gets the highest possible address.

- The **contiguous** keyword tells the linker to locate the sections in the group in a single address range. Within a contiguous group the input sections are located in arbitrary order, however the group occupies one contiguous range of memory. Due to alignment of sections there can be 'alignment gaps' between the sections.

When you define a group that is both **ordered** and **contiguous**, this is called a *sequential* group. In a sequential group the linker places sections in the same order in the address space as they appear in the group and it occupies a contiguous range of memory.

- The **clustered** keyword tells the linker to locate the sections in the group in a number of *contiguous* blocks. It tries to keep the number of these blocks to a minimum. If enough memory is available, the

group will be located as if it was specified as **contiguous**. Otherwise, it gets split into two or more blocks.

If a contiguous or clustered group contains *alignment gaps*, the linker can locate sections that are not part of the group in these gaps. To prevent this, you can use the **fill** keyword. If the group is located in RAM, the gaps are treated as reserved (scratch) space. If the group is located in ROM, the alignment gaps are filled with zeros by default. You can however change the fill pattern by specifying a bit pattern. The result of the expression, or list of expressions, is used as values to write to memory, each in MAU.

- The **overlay** keyword tells the linker to overlay the sections in the group. The linker places all sections in the address space using a contiguous range of addresses. (Thus an overlay group is automatically also a contiguous group.) To overlay the sections, all sections in the overlay group share the same run-time address.

For each input section within the overlay the linker automatically defines two symbols. The symbol `_lc_cb_section_name` is defined as the load-time start address of the section. The symbol `_lc_ce_section_name` is defined as the load-time end address of the section. Assembly code may be used to copy the overlaid sections.

If sections in the overlay group contain references between groups, the linker reports an error. The keyword **allow_cross_references** tells the linker to accept cross-references. Normally, it does not make sense to have references between sections that are overlaid.

```
group ovl (overlay)
{
    group a
    {
        select "my_ovl_p1";
        select "my_ovl_p2";
    }
    group b
    {
        select "my_ovl_q1";
    }
}
```

It may be possible that one of the sections in the overlay group already has been defined in another group where it received a load-time address. In this case the linker does not overrule this load-time address and excludes the section from the overlay group.

3. Restrict the possible addresses for the sections in a group.

The load-time address specifies where the group's elements are loaded in memory at download time. The run-time address specifies where sections are located at run-time, that is when the program is executing. If you do not explicitly restrict the address in the LSL file, the linker assigns addresses to the sections based on the restrictions relative to other sections in the LSL file and section alignments. The program is responsible for copying overlay sections at appropriate moment from its load-time location to its run-time location (this is typically done by the startup code).

- The `run_addr` keyword defines the run-time address. If the run-time location of a group is set explicitly, the given order between groups specify whether the run-time address propagates to the parent group or not. The location of the sections in a group can be restricted either to a single absolute address, or to a number of address ranges (not including the end address). With an expression you can specify that the group should be located at the absolute address specified by the expression:

```
group (ordered, run_addr = 0xa00f0000)
```

A group with an absolute address must be ordered, the first section in the group is located at the specified absolute address.

You can use the `['offset']` variant to locate the group at the given absolute offset in memory:

```
group (ordered, run_addr = mem:A[0x1000])
```

A group with an absolute address must be ordered, the first section in the group is located at the specified absolute offset in memory.

A range can be an absolute space address range, written as `[expr .. expr]`, a complete memory device, written as `mem:mem_name`, or a memory address range, `mem:mem_name[expr .. expr]`

```
group (run_addr = mem:my_dram)
```

You can use the `|` to specify an address range of more than one physical memory device:

```
group (run_addr = mem:A | mem:B)
```

When used in top-level section layouts, a memory name refers to a board-level memory. You can select on-chip memory with `mem:proc_name:mem_name`. If the memory has multiple parallel mappings towards the current address space, you can select a specific named mapping in the memory by appending `/map_name` to the memory specifier. The linker then maps memory offsets only through that mapping, so the address(es) where the sections in the group are located are determined by that memory mapping.

```
group (run_addr = mem:CPU1:A/cached)
```

- The `load_addr` keyword changes the meaning of the section selection in the group: the linker selects the load-time ROM copy of the named section(s) instead of the regular sections. Just like `run_addr` you can specify an absolute address or an address range.

```
group (contiguous, load_addr)
{
    select "mydata"; // select ROM copy of mydata:
                   // "[mydata]"
}
```

The load-time and run-time addresses of a group cannot be set at the same time. If the load-time property is set for a group, the group (only) restricts the positioning at load-time of the group's sections. It is not possible to set the address of a group that has a not-unrestricted parent group.

The properties of the load-time and run-time start address are:

TASKING VX-toolset for MCS User Guide

- At run-time, before using an element in an overlay group, the application copies the sections from their load location to their run-time location, but only if these two addresses are different. For non-overlay sections this happens at program start-up.
- The start addresses cannot be set to absolute values for unrestricted groups.
- For non-overlay groups that do not have an overlay parent, the load-time start address equals the run-time start address.
- For any group, if the run-time start address is not set, the linker selects an appropriate address.
- If an ordered group or sequential group has an absolute address and contains sections that have separate page restrictions (not defined in LSL), all those sections are located in a single page. In other cases, for example when an unrestricted group has an address range assigned to it, the paged sections may be located in different pages.

For overlays, the linker reserves memory at the run-time start address as large as the largest element in the overlay group.

- The **page** keyword tells the linker to place the group in one page. Instead of specifying a run-time address, you can specify a page and optional a page number. Page numbers start from zero. If you omit the page number, the linker chooses a page.

The **page** keyword refers to pages in the address space as defined in the architecture definition.

- With the **page_size** keyword you can override the page alignment and size set on the address space. When you set the page size to zero, the linker removes simple (auto generated) page restrictions from the selected sections. See also the **page_size** keyword in [Section 13.4.3, Defining Address Spaces](#).
- With the **priority** keyword you can change the order in which sections are located. This is useful when some sections are considered important for good performance of the application and a small amount of fast memory is available. The value is a number for which the default is 1, so higher priorities start at 2. Sections with a higher priority are located before sections with a lower priority, unless their relative locate priority is already determined by other restrictions like **run_addr** and **page**.

```
group (priority=2)
{
    select "importantcode1";
    select "importantcode2";
}
```

- With the **safety_class** keyword you can assign a safety class to the sections in the group. The safety class must be a positive integer value. The default value is zero. The meaning of the safety class value is user defined.

```
group ASIL_A (safety_class=3)
{
    select "/*.ASIL_A.*" (attributes=-w);
}
```

13.8.3. Creating or Modifying Special Sections

Instead of selecting sections, you can also create a reserved section or an output section or modify special sections like a stack or a heap. Because you cannot define these sections in the input files, you must use the linker to create them.

Stack

- The keyword **stack** tells the linker to reserve memory for the stack. The name for the stack section refers to the stack as defined in the architecture definition. If no name was specified in the architecture definition, the default name is `stack`.

With the keyword **size** you can specify the size for the stack. If the size is not specified, the linker uses the size given by the **min_size** argument as defined for the stack in the architecture definition. Normally the linker automatically tries to maximize the size, unless you specified the keyword **fixed**.

```
group ( ... )
{
    stack "mystack" ( size = 2k );
}
```

The linker creates two labels to mark the begin and end of the stack, `_1c_ub_stack_name` for the begin of the stack and `_1c_ue_stack_name` for the end of the stack. The linker allocates space for the stack when there is a reference to either of the labels.

See also the **stack** keyword in [Section 13.4.3, *Defining Address Spaces*](#).

Heap

- The keyword **heap** tells the linker to reserve a dynamic memory range for the `malloc()` function. Each heap section has a name. With the keyword **size** you can change the size for the heap. If the **size** is not specified, the linker uses the size given by the **min_size** argument as defined for the heap in the architecture definition. Normally the linker automatically tries to maximize the size, unless you specified the keyword **fixed**.

```
group ( ... )
{
    heap "myheap" ( size = 2k );
}
```

The linker creates two labels to mark the begin and end of the heap, `_1c_ub_heap_name` for the begin of the heap and `_1c_ue_heap_name` for the end of the heap. The linker allocates space for the heap when a reference to either of the section labels exists in one of the input object files.

Reserved section

- The keyword **reserved** tells the linker to create an area or section of a given size. The linker will not locate any other sections in the memory occupied by a reserved section, with some exceptions. Each reserved section has a name. With the keyword **size** you can specify a size for a given reserved area or section.

TASKING VX-toolset for MCS User Guide

```
group ( ... )
{
    reserved "myreserved" ( size = 2k );
}
```

The optional **fill** field contains a bit pattern that the linker writes to all memory addresses that remain unoccupied during the locate process. The result of the expression, or list of expressions, is used as values to write to memory, each in MAU. The first MAU of the fill pattern is always the first MAU in the section.

By default, no sections can overlap with a reserved section. With **alloc_allowed=absolute** sections that are located at an absolute address due to an absolute group restriction can overlap a reserved section. The same applies for reserved sections with **alloc_allowed=ranged** set. Sections restricted to a fixed address range can also overlap a reserved section.

With the **attributes** field you can set the access type of the reserved section. The linker locates the reserved section in its space with the restrictions that follow from the used attributes, **r**, **w** or **x** or a valid combination of them. The allowed attributes are shown in the following table. A value between < and > in the table means this value is set automatically by the linker.

Properties set in LSL		Resulting section properties		
attributes	filled	access	memory	content
x	yes		<rom>	executable
r	yes	r	<rom>	data
r	no	r	<rom>	scratch
rx	yes	r	<rom>	executable
rw	yes	rw	<ram>	data
rw	no	rw	<ram>	scratch
rwx	yes	rw	<ram>	executable

```
group ( ... )
{
    reserved "myreserved" ( size = 2k,
        attributes = rw, fill = 0xaa );
}
```

If you do not specify any attributes, the linker will reserve the given number of maus, no matter what type of memory lies beneath. If you do not specify a fill pattern, no section is generated.

The linker creates two labels to mark the begin and end of the section, **_lc_ub_name** for the begin of the section and **_lc_ue_name** for the end of the reserved section.

Output sections

- The keyword **section** tells the linker to accumulate sections obtained from object files ("input sections") into an output section of a fixed size in the locate phase. You can select the input sections with **select** statements. You can use groups inside output sections, but you can only set the **align**, **attributes**, **nocopy** and **load_addr** properties and the **load_addr** property cannot have an address specified.

The **fill** field contains a bit pattern that the linker writes to all unused space in the output section. When all input sections have an image (code/data) you must specify a fill pattern. If you do not specify a fill pattern, all input sections must be scratch sections. The fill pattern is aligned at the start of the output section.

As with a reserved section you can use the **attributes** field to set the access type of the output section.

```
group ( ... )
{
    section "myoutput" ( size = 4k, attributes = rw,
                       fill = 0xaa )
    {
        select "myinput1";
        select "myinput2";
    }
}
```

The available room for input sections is determined by the **size**, **blocksize** and **overflow** fields. With the keyword **size** you specify the fixed size of the output section. Input sections are placed from output section start towards higher addresses (offsets). When the end of the output section is reached and one or more input sections are not yet placed, an error is emitted. If however, the **overflow** field is set to another output section, remaining sections are located as if they were selected for the overflow output section.

```
group ( ... )
{
    section "tsk1_data" (size=4k, attributes=rw, fill=0,
                      overflow = "overflow_data")
    {
        select ".data.tsk1.*"
    }
    section "tsk2_data" (size=4k, attributes=rw, fill=0,
                      overflow = "overflow_data")
    {
        select ".data.tsk2.*"
    }
    section "overflow_data" (size=4k, attributes=rx,
                           fill=0)
    {
    }
}
```

With the keyword **blocksize**, the size of the output section will adapt to the size of its content. For example:

```
group flash_area (run_addr = 0x10000)
{
    section "flash_code" (blocksize=4k, attributes=rx,
                        fill=0)
    {
```

```
        select "*.flash";
    }
}
```

If the content of the section is 1 mau, the size will be 4 kB, if the content is 11 kB, the section will be 12 kB, etc. If you use **size** in combination with **blocksize**, the **size** value is used as default (minimal) size for this section. If it is omitted, the default size will be of **blocksize**. It is not allowed to omit both **size** and **blocksize** from the section definition.

The linker creates two labels to mark the begin and end of the section, **_lc_ub_name** for the begin of the section and **_lc_ue_name** for the end of the output section.

When the **copy** property is set on an enclosing group, a ROM copy is created for the output section and the output section itself is made writable causing it to be located in RAM by default. For this to work, the output section and its input sections must be read-only and the output section must have a **fill** property.

A copy table can also be inserted into an output section, but only if two additional conditions are met:

- The copy table is the last section added to the output section.
- There must be sufficient room in the output section to accommodate the additional size of the copy table.

A copy table will likely increase in size after being added to the output section, so if you would add sections after the copy table selection, this would overwrite part of the copy table. The linker will emit an error message if either of the conditions is not met.

```
group ( ... )
{
    section "myoutput_ttbl" ( size = 4k, attributes = r, fill = 0 )
    {
        select "myinput";
        select "table"; // select the copy table
    }
}
```

Copy table

- The keyword **copytable** tells the linker to select a section that is used as *copy table*. The content of the copy table is created by the linker. It contains the start address and length of all sections that should be initialized by the startup code.

The linker creates two labels to mark the begin and end of the section, **_lc_ub_table** for the begin of the section and **_lc_ue_table** for the end of the copy table. The linker generates a copy table when a reference to either of the section labels exists in one of the input object files.

Memory copy sections

- If a memory (usually RAM) needs to be initialized by a different core than the one(s) that will use it, a copy of the contents of the memory can be placed in a section using a **memcopy** statement in a

section_layout. All data (including code) present in the specified memory is then placed in a new section with the provided name and appropriate attributes. Unused areas in the memory are filled in the section using the supplied fill pattern or with zeros if no fill pattern is specified. If the memory contains a memory copy section the result is undefined. The actual initialization of the memory at run-time needs to be done separately, this LSL feature only directs the linker to make the data located in the memory available for initialization. Note that a memory of type **ram** cannot hold initialized data, use type **blockram** instead.

Structures

- A **struct** statement in a **section_layout** creates a section and fills it with numbers that each occupy one or more MAUs. The new section must be named by providing a double-quoted string after the **struct** keyword. Each element has the form *expr*: *number*;, where the expression provides the value to insert in the section and the number determines the number of MAUs occupied by the expression value. Elements are placed in the section in the order in which they appear in the **struct** body without any gaps between them. Multi-MAU elements are split into MAUs according to the endianness of the target. A **struct** section is read-only and it cannot be copied to RAM at startup (using the **copy** group attribute). No default alignment is set.

For example,

```
struct "mystruct"
{
    0x1234                                : 2;
    addressof( mem:foo )                  : 4;
    addressof( mem:foo ) + sizeof( mem:foo ) : 4;
    checksum( crc32w,
        addressof( mem:foo ),
        addressof( mem:foo ) + sizeof( mem:foo ) ) : 4}
}
```

13.8.4. Creating Symbols

You can tell the linker to create symbols before locating by putting assignments in the section layout definition. Symbol names are represented by double-quoted strings. Any string is allowed, but object files may not support all characters for symbol names. You can use two different assignment operators. With the simple assignment operator '=', the symbol is created unconditionally. With the ':=' operator, the symbol is only created if it already exists as an undefined reference in an object file.

The expression that represents the value to assign to the symbol may contain references to other symbols. If such a referred symbol is a special section symbol, creation of the symbol in the left hand side of the assignment will cause creation of the special section.

```
section_layout
{
    "_lc_cp" := "_lc_ub_table";
    // when the symbol _lc_cp occurs as an undefined reference
    // in an object file, the linker generates a copy table
}
```

13.8.5. Conditional Group Statements

Within a group, you can conditionally select sections or create special sections.

- With the `if` keyword you can specify a condition. The succeeding section statement is executed if the condition evaluates to TRUE (1).
- The optional `else` keyword is followed by a section statement which is executed in case the if-condition evaluates to FALSE (0).

```
group ( ... )
{
    if ( exists( "mysection" ) )
        select "mysection";
    else
        reserved "myreserved" ( size=2k );
}
```

Chapter 14. Debug Target Configuration Files

DTC files (Debug Target Configuration files) define all possible configurations for a debug target. A debug target can be target hardware such as an evaluation board or a simulator. The DTC files are used by Eclipse to configure the project and the debugger. The information is used by the Target Board Configuration wizard and the debug configuration. DTC files are located in the `etc` directory of the installed product and use `.dtc` as filename suffix.

Based on the DTC files, the Target Board Configuration wizard adjust the project's LSL file and creates a debug launch configuration.

14.1. Custom Board Support

When you need support for a custom board and the board requires a different configuration than those that are in the product, it is necessary to create a dedicated DTC file.

To add a custom board

1. From the `etc` directory of the product, make a copy of a `.dtc` file and put it in your project directory (in the current workspace).

In Eclipse, the DTC file should now be visible as part of your project.

2. Edit the file and give it a name that reflects the custom board.

The Import Board Configuration wizard in Eclipse adds DTC files that are present in your current project to the list of available target boards.

Syntax of a DTC file

DTC files are XML files and use the XML Schema file `dtc.xsd`, also present in the `etc` directory of the installed product.

Inspect the DTC XML schema file `dtc.xsd` for a description of the allowed elements and the available attributes. Use a delivered `.dtc` file as a starting point for creating a custom board specification.

Basically a DTC file consists of the definition of the debug target (`debugTarget` element) which embodies one or more configurations (`configuration` element) and one or more communication methods (`communicationMethod` element).

DTC macros in LSL

To protect wizards/dialogs from changing the LSL file, you can protect the LSL file by adding the macro `__DTC_IGNORE`. This can be useful for projects that need the same LSL file, but still need to run on different target boards.

```
#define __DTC_IGNORE
```

14.2. Description of DTC Elements and Attributes

The following table contains a description of the DTC elements and attributes. For each element a list of allowed elements is listed and the available attributes are described.

Element / Attribute	Description	Allowed Elements
debugTarget	The debug target.	flashChips, lsl, communicationMethod, def, processor, resource, initialize
name	The name of the configuration.	
manufacturer	The manufacturer of the debug target.	
processor	Defines a processor that can be present on the debug target. Multiple processor definitions are allowed. The user should select the actual processor on the debug target.	-
name	A descriptive name of the processor derivative.	
cpu	Defines the CPU name.	
communicationMethod	Defines a communication method. A communication method is the channel that is used to communicate with the target.	ref, resource, initialize, configuration, lsl, processor
name	A descriptive name of the communication method.	
debugInstrument	The debug instrument DLL/Shared library file to be used for this communication method. Do not supply a path or a filename suffix.	
gdiMethod	This is the method used for communication. Allowed values: rs232, tcpip, can, none	
def	Defines a set of elements as a macro. The macro can be expanded using the ref element.	lsl, resource, initialize, ref, configuration, flashMonitor
id	The macro name.	
resource	Defines a resource definition that can be used by Eclipse, the debugger or by the debug instrument.	-
id	The identifier name used by the debugger or debug instrument to retrieve the value.	
value	The value assigned to the resource.	
ref	Reference to a macro defined with a def element. The elements contained in the def element with the same name will be expanded at the location of the ref. Multiple refs to the same def are allowed.	-
id	The name of the referenced macro.	

Element / Attribute	Description	Allowed Elements
configuration	Defines a configuration.	ref, initialize, resource, lsl, flashMonitor, processor
name	The descriptive name of the configuration.	
initialize	This element defines an initialization expression. Each initialize element contains a <code>resourceId</code> attribute. If the DI requests this resource the debugger will compose a string from all initialize elements with the same <code>resourceId</code> . This DI can use this string to initialize registers by passing it to the debugger as an expression to be evaluated.	-
resourceId	The name of the resource to be used.	
name	The name of the register to be initialized.	
value	When the <code>cstart</code> attribute is false, this is the value to be used, otherwise, it is the default value when using this configuration. It will be used by the startup code editor to set the default register values.	
cstart	A boolean value. If true the debugger should ask the C startup code editor for the value, otherwise the contents of the value attribute is used. The default value is true.	
flashMonitor	This element specifies the flash programming monitor to be used for this configuration.	-
monitor	Filename of the monitor, usually an Intel Hex or S-Record file.	
workspaceAddress	The address of the workspace of the flash programming monitor.	
flashSectorBufferSize	Specifies the buffer size for buffering a flash sector.	
chip	This element defines a flash chip. It must be used by the flash properties page to add it on request to the list of flash chips.	debugTarget
vendor	The vendor of this flash chip.	
chip	The name of the chip.	
width	The width of the chip in bits.	
chips	The number of chips present on the board.	
baseAddress	The base address of the chip.	
chipSize	The size of the chip in bytes.	
flashChips	Specify a list of flash chips that can be available on this debug target.	chip

TASKING VX-toolset for MCS User Guide

Element / Attribute	Description	Allowed Elements
lsl	Defines LSL pieces belonging to the configuration part. The LSL text must be defined between the start and end tag of this element. All LSL texts of the active selection will be placed in the project's LSL file.	-

Chapter 15. CERT C Secure Coding Standard

The CERT C Secure Coding Standard provides rules and recommendations for secure coding in the C programming language. The goal of these rules and recommendations is to eliminate insecure coding practices and undefined behaviors that can lead to exploitable vulnerabilities. The application of the secure coding standard will lead to higher-quality systems that are robust and more resistant to attack.

This chapter contains an overview of the CERT C Secure Coding Standard recommendations and rules that are supported by the TASKING VX-toolset.

For details see the [CERT C Secure Coding Standard](#) web site. For general information about CERT secure coding, see www.cert.org/secure-coding.

Identifiers

Each rule and recommendation is given a unique identifier. These identifiers consist of three parts:

- a three-letter mnemonic representing the section of the standard
- a two-digit numeric value in the range of 00-99
- the letter "C" indicates that this is a C language guideline

The three-letter mnemonic is used to group similar coding practices and to indicate to which category a coding practice belongs.

The numeric value is used to give each coding practice a unique identifier. Numeric values in the range of 00-29 are reserved for recommendations, while values in the range of 30-99 are reserved for rules.

C compiler invocation

With the C compiler option `--cert` you can enable one or more checks for the CERT C Secure Coding Standard recommendations/rules. With `--diag=cert` you can see a list of the available checks, or you can use a three-letter mnemonic to list only the checks in a particular category. For example, `--diag=pre` lists all supported checks in the preprocessor category.

15.1. Preprocessor (PRE)

PRE01-C Use parentheses within macros around parameter names

Parenthesize all parameter names in macro definitions to avoid precedence problems.

PRE02-C Macro replacement lists should be parenthesized

Macro replacement lists should be parenthesized to protect any lower-precedence operators from the surrounding expression. The example below is syntactically correct, although the `!=` operator was omitted. Enclosing the constant `-1` in parenthesis will prevent the incorrect interpretation and force a compiler error:

```
#define EOF -1 // should be (-1)
int getchar(void);
void f(void)
{
    if (getchar() EOF) // != operator omitted
    {
        /* ... */
    }
}
```

PRE10-C Wrap multi-statement macros in a do-while loop

When multiple statements are used in a macro, enclose them in a `do-while` statement, so the macro can appear safely inside `if` clauses or other places that expect a single statement or a statement block. Braces alone will not work in all situations, as the macro expansion is typically followed by a semicolon.

PRE11-C Do not conclude a single statement macro definition with a semicolon

Macro definitions consisting of a single statement should not conclude with a semicolon. If required, the semicolon should be included following the macro expansion. Inadvertently inserting a semicolon can change the control flow of the program.

15.2. Declarations and Initialization (DCL)

DCL30-C Declare objects with appropriate storage durations

The lifetime of an automatic object ends when the function returns, which means that a pointer to the object becomes invalid.

DCL31-C Declare identifiers before using them

The ISO C90 standard allows implicit typing of variables and functions. Because implicit declarations lead to less stringent type checking, they can often introduce unexpected and erroneous behavior or even security vulnerabilities. The ISO C99 standard requires type identifiers and forbids implicit function declarations. For backwards compatibility reasons, the VX-toolset C compiler assumes an implicit declaration and continues translation after issuing a warning message (W505 or W535).

DCL32-C Guarantee that mutually visible identifiers are unique

The compiler encountered two or more identifiers that are identical in the first 31 characters. The ISO C99 standard allows a compiler to ignore characters past the first 31 in an identifier. Two distinct identifiers that are identical in the first 31 characters may lead to problems when the code is ported to a different compiler.

DCL35-C Do not invoke a function using a type that does not match the function definition

This warning is generated when a function pointer is set to refer to a function of an incompatible type. Calling this function through the function pointer will result in undefined behavior. Example:

```
void my_function(int a);
int main(void)
{
    int (*new_function)(int a) = my_function;
    return (*new_function)(10); /* the behavior is undefined */
}
```

15.3. Expressions (EXP)

EXP01-C Do not take the size of a pointer to determine the size of the pointed-to type

The size of the object(s) allocated by `malloc()`, `calloc()` or `realloc()` should be a multiple of the size of the base type of the result pointer. Therefore, the `sizeof` expression should be applied to this base type, and not to the pointer type.

EXP12-C Do not ignore values returned by functions

The compiler gives this warning when the result of a function call is ignored at some place, although it is not ignored for other calls to this function. This warning will not be issued when the function result is ignored for all calls, or when the result is explicitly ignored with a `(void)` cast.

EXP30-C Do not depend on order of evaluation between sequence points

Between two sequence points, an object should only be modified once. Otherwise the behavior is undefined.

EXP32-C Do not access a volatile object through a non-volatile reference

If an attempt is made to refer to an object defined with a volatile-qualified type through use of an lvalue with non-volatile-qualified type, the behavior is undefined.

EXP33-C Do not reference uninitialized memory

Uninitialized automatic variables default to whichever value is currently stored on the stack or in the register allocated for the variable. Consequently, uninitialized memory can cause a program to behave in an unpredictable or unplanned manner and may provide an avenue for attack.

EXP34-C Ensure a null pointer is not dereferenced

Attempting to dereference a null pointer results in undefined behavior, typically abnormal program termination.

EXP37-C Call functions with the arguments intended by the API

When a function is properly declared with function prototype information, an incorrect call will be flagged by the compiler. When there is no prototype information available at the call, the compiler cannot check the number of arguments and the types of the arguments. This message is issued to warn about this situation.

EXP38-C Do not call `offsetof()` on bit-field members or invalid types

The behavior of the `offsetof()` macro is undefined when the member designator parameter designates a bit-field.

15.4. Integers (INT)

INT30-C Ensure that unsigned integer operations do not wrap

A constant with an unsigned integer type is truncated, resulting in a wrap-around.

INT34-C Do not shift a negative number of bits or more bits than exist in the operand

The shift count of the shift operation may be negative or greater than or equal to the size of the left operand. According to the C standard, the behavior of such a shift operation is undefined. Make sure the shift count is in range by adding appropriate range checks.

INT35-C Evaluate integer expressions in a larger size before comparing or assigning to that size

If an integer expression is compared to, or assigned to a larger integer size, that integer expression should be evaluated in that larger size by explicitly casting one of the operands.

15.5. Floating Point (FLP)

FLP30-C Do not use floating point variables as loop counters

To avoid problems with limited precision and rounding, floating point variables should not be used as loop counters.

FLP35-C Take granularity into account when comparing floating point values

Floating point arithmetic in C is inexact, so floating point values should not be tested for exact equality or inequality.

FLP36-C Beware of precision loss when converting integral types to floating point

Conversion from integral types to floating point types without sufficient precision can lead to loss of precision.

15.6. Arrays (ARR)

ARR01-C Do not apply the sizeof operator to a pointer when taking the size of an array

A function parameter declared as an array, is converted to a pointer by the compiler. Therefore, the sizeof operator applied to this parameter yields the size of a pointer, and not the size of an array.

ARR34-C Ensure that array types in expressions are compatible

Using two or more incompatible arrays in an expression results in undefined behavior.

ARR35-C Do not allow loops to iterate beyond the end of an array

Reading or writing of data outside the bounds of an array may lead to incorrect program behavior or execution of arbitrary code.

15.7. Characters and Strings (STR)

STR30-C Do not attempt to modify string literals

Writing to a string literal has undefined behavior, as identical strings may be shared and/or allocated in read-only memory.

STR33-C Size wide character strings correctly

Wide character strings may be improperly sized when they are mistaken for narrow strings or for multi-byte character strings.

STR34-C Cast characters to unsigned types before converting to larger integer sizes

A signed character is sign-extended to a larger signed integer value. Use an explicit cast, or cast the value to an unsigned type first, to avoid unexpected sign-extension.

STR36-C Do not specify the bound of a character array initialized with a string literal

The compiler issues this warning when the character buffer initialized by a string literal does not provide enough room for the terminating null character.

15.8. Memory Management (MEM)

MEM00-C Allocate and free memory in the same module, at the same level of abstraction

The compiler issues this warning when the result of the call to malloc(), calloc() or realloc() is discarded, and therefore not free()d, resulting in a memory leak.

MEM08-C Use realloc() only to resize dynamically allocated arrays

Only use realloc() to resize an array. Do not use it to transform an object to an object of a different type.

MEM30-C Do not access freed memory

When memory is freed, its contents may remain intact and accessible because it is at the memory manager's discretion when to reallocate or recycle the freed chunk. The data at the freed location may appear valid. However, this can change unexpectedly, leading to unintended program behavior. As a result, it is necessary to guarantee that memory is not written to or read from once it is freed.

MEM31-C Free dynamically allocated memory exactly once

Freeing memory multiple times has similar consequences to accessing memory after it is freed. The underlying data structures that manage the heap can become corrupted. To eliminate double-free vulnerabilities, it is necessary to guarantee that dynamic memory is freed exactly once.

MEM32-C Detect and handle memory allocation errors

The result of `realloc()` is assigned to the original pointer, without checking for failure. As a result, the original block of memory is lost when `realloc()` fails.

MEM33-C Use the correct syntax for flexible array members

Use the ISO C99 syntax for flexible array members instead of an array member of size 1.

MEM34-C Only free memory allocated dynamically

Freeing memory that is not allocated dynamically can lead to corruption of the heap data structures.

MEM35-C Allocate sufficient memory for an object

The compiler issues this warning when the size of the object(s) allocated by `malloc()`, `calloc()` or `realloc()` is smaller than the size of an object pointed to by the result pointer. This may be caused by a `sizeof` expression with the wrong type or with a pointer type instead of the object type.

15.9. Environment (ENV)

ENV32-C All `atexit` handlers must return normally

The compiler issues this warning when an `atexit()` handler is calling a function that does not return. No `atexit()` registered handler should terminate in any way other than by returning.

15.10. Signals (SIG)

SIG30-C Call only asynchronous-safe functions within signal handlers

SIG32-C Do not call `longjmp()` from inside a signal handler

Invoking the `longjmp()` function from within a signal handler can lead to undefined behavior if it results in the invocation of any non-asynchronous-safe functions, likely compromising the integrity of the program.

15.11. Miscellaneous (MSC)

MSC32-C Ensure your random number generator is properly seeded

Ensure that the random number generator is properly seeded by calling `srand()`.

Chapter 16. MISRA C Rules

This chapter contains an overview of the supported and unsupported MISRA C rules.

16.1. MISRA C:1998

This section lists all supported and unsupported MISRA C:1998 rules.

See also [Section 3.6.2, C Code Checking: MISRA C](#).

A number of MISRA C rules leave room for interpretation. Other rules can only be checked in a limited way. In such cases the implementation decisions and possible restrictions for these rules are listed.

x means that the rule is not supported by the TASKING C compiler. (R) is a required rule, (A) is an advisory rule.

1. (R) The code shall conform to standard C, without language extensions.
- x** 2. (A) Other languages should only be used with an interface standard.
3. (A) Inline assembly is only allowed in dedicated C functions.
- x** 4. (A) Provision should be made for appropriate run-time checking.
5. (R) Only use characters and escape sequences defined by ISO C.
- x** 6. (R) Character values shall be restricted to a subset of ISO 10646-1.
7. (R) Trigraphs shall not be used.
8. (R) Multibyte characters and wide string literals shall not be used.
9. (R) Comments shall not be nested.
10. (A) Sections of code should not be "commented out".

In general, it is not possible to decide whether a piece of comment is C code that is commented out, or just some pseudo code. Instead, the following heuristics are used to detect possible C code inside a comment:

- a line ends with ';', or
- a line starts with '}', possibly preceded by white space

11. (R) Identifiers shall not rely on significance of more than 31 characters.
12. (A) The same identifier shall not be used in multiple name spaces.
13. (A) Specific-length typedefs should be used instead of the basic types.
14. (R) Use `unsigned char` or `signed char` instead of plain `char`.
- x** 15. (A) Floating-point implementations should comply with a standard.
16. (R) The bit representation of floating-point numbers shall not be used.
A violation is reported when a pointer to a floating-point type is converted to a pointer to an integer type.

TASKING VX-toolset for MCS User Guide

17. (R) `typedef` names shall not be reused.
18. (A) Numeric constants should be suffixed to indicate type.
A violation is reported when the value of the constant is outside the range indicated by the suffixes, if any.
19. (R) Octal constants (other than zero) shall not be used.
20. (R) All object and function identifiers shall be declared before use.
21. (R) Identifiers shall not hide identifiers in an outer scope.
22. (A) Declarations should be at function scope where possible.
- x 23. (A) All declarations at file scope should be static where possible.
24. (R) Identifiers shall not have both internal and external linkage.
- x 25. (R) Identifiers with external linkage shall have exactly one definition.
26. (R) Multiple declarations for objects or functions shall be compatible.
- x 27. (A) External objects should not be declared in more than one file.
28. (A) The `register` storage class specifier should not be used.
29. (R) The use of a tag shall agree with its declaration.
30. (R) All automatics shall be initialized before being used .
This rule is checked using worst-case assumptions. This means that violations are reported not only for variables that are guaranteed to be uninitialized, but also for variables that are uninitialized on some execution paths.
31. (R) Braces shall be used in the initialization of arrays and structures.
32. (R) Only the first, or all enumeration constants may be initialized.
33. (R) The right hand operand of `&&` or `||` shall not contain side effects.
34. (R) The operands of a logical `&&` or `||` shall be primary expressions.
35. (R) Assignment operators shall not be used in Boolean expressions.
36. (A) Logical operators should not be confused with bitwise operators.
37. (R) Bitwise operations shall not be performed on signed integers.
38. (R) A shift count shall be between 0 and the operand width minus 1.
This violation will only be checked when the shift count evaluates to a constant value at compile time.
39. (R) The unary minus shall not be applied to an unsigned expression.
40. (A) `sizeof` should not be used on expressions with side effects.
- x 41. (A) The implementation of integer division should be documented.
42. (R) The comma operator shall only be used in a `for` condition.
43. (R) Don't use implicit conversions which may result in information loss.
44. (A) Redundant explicit casts should not be used.
45. (R) Type casting from any type to or from pointers shall not be used.

46. (R) The value of an expression shall be evaluation order independent.
This rule is checked using worst-case assumptions. This means that a violation will be reported when a possible alias may cause the result of an expression to be evaluation order dependent.
47. (A) No dependence should be placed on operator precedence rules.
48. (A) Mixed arithmetic should use explicit casting.
49. (A) Tests of a (non-Boolean) value against 0 should be made explicit.
50. (R) F.P. variables shall not be tested for exact equality or inequality.
51. (A) Constant unsigned integer expressions should not wrap-around.
52. (R) There shall be no unreachable code.
53. (R) All non-null statements shall have a side-effect.
54. (R) A null statement shall only occur on a line by itself.
55. (A) Labels should not be used.
56. (R) The `goto` statement shall not be used.
57. (R) The `continue` statement shall not be used.
58. (R) The `break` statement shall not be used (except in a `switch`).
59. (R) An `if` or loop body shall always be enclosed in braces.
60. (A) All `if, else if` constructs should contain a final `else`.
61. (R) Every non-empty `case` clause shall be terminated with a `break`.
62. (R) All `switch` statements should contain a final `default` case.
63. (A) A `switch` expression should not represent a Boolean case.
64. (R) Every `switch` shall have at least one `case`.
65. (R) Floating-point variables shall not be used as loop counters.
66. (A) A `for` should only contain expressions concerning loop control.
A violation is reported when the loop initialization or loop update expression modifies an object that is not referenced in the loop test.
67. (A) Iterator variables should not be modified in a `for` loop.
68. (R) Functions shall always be declared at file scope.
69. (R) Functions with variable number of arguments shall not be used.
70. (R) Functions shall not call themselves, either directly or indirectly.
A violation will be reported for direct or indirect recursive function calls in the source file being checked. Recursion via functions in other source files, or recursion via function pointers is not detected.
71. (R) Function prototypes shall be visible at the definition and call.
72. (R) The function prototype of the declaration shall match the definition.
73. (R) Identifiers shall be given for all prototype parameters or for none.
74. (R) Parameter identifiers shall be identical for declaration/definition.
75. (R) Every function shall have an explicit return type.

TASKING VX-toolset for MCS User Guide

- 76. (R) Functions with no parameters shall have a `void` parameter list.
- 77. (R) An actual parameter type shall be compatible with the prototype.
- 78. (R) The number of actual parameters shall match the prototype.
- 79. (R) The values returned by `void` functions shall not be used.
- 80. (R) Void expressions shall not be passed as function parameters.
- 81. (A) `const` should be used for reference parameters not modified.
- 82. (A) A function should have a single point of exit.
- 83. (R) Every exit point shall have a `return` of the declared return type.
- 84. (R) For `void` functions, `return` shall not have an expression.
- 85. (A) Function calls with no parameters should have empty parentheses.
- 86. (A) If a function returns error information, it should be tested.
A violation is reported when the return value of a function is ignored.
- 87. (R) `#include` shall only be preceded by other directives or comments.
- 88. (R) Non-standard characters shall not occur in `#include` directives.
- 89. (R) `#include` shall be followed by either `<filename>` or `"filename"`.
- 90. (R) Plain macros shall only be used for constants/qualifiers/specifiers.
- 91. (R) Macros shall not be `#define`'d and `#undef`'d within a block.
- 92. (A) `#undef` should not be used.
- 93. (A) A function should be used in preference to a function-like macro.
- 94. (R) A function-like macro shall not be used without all arguments.
- 95. (R) Macro arguments shall not contain pre-preprocessing directives.
A violation is reported when the first token of an actual macro argument is `'#'`.
- 96. (R) Macro definitions/parameters should be enclosed in parentheses.
- 97. (A) Don't use undefined identifiers in pre-processing directives.
- 98. (R) A macro definition shall contain at most one `#` or `##` operator.
- 99. (R) All uses of the `#pragma` directive shall be documented.
This rule is really a documentation issue. The compiler will flag all `#pragma` directives as violations.
- 100. (R) `defined` shall only be used in one of the two standard forms.
- 101. (A) Pointer arithmetic should not be used.
- 102. (A) No more than 2 levels of pointer indirection should be used.
A violation is reported when a pointer with three or more levels of indirection is declared.
- 103. (R) No relational operators between pointers to different objects.
In general, checking whether two pointers point to the same object is impossible. The compiler will only report a violation for a relational operation with incompatible pointer types.
- 104. (R) Non-constant pointers to functions shall not be used.
- 105. (R) Functions assigned to the same pointer shall be of identical type.

- 106. (R) Automatic address may not be assigned to a longer lived object.
- 107. (R) The null pointer shall not be de-referenced.
A violation is reported for every pointer dereference that is not guarded by a NULL pointer test.
- 108. (R) All `struct/union` members shall be fully specified.
- 109. (R) Overlapping variable storage shall not be used.
A violation is reported for every `union` declaration.
- 110. (R) Unions shall not be used to access the sub-parts of larger types.
A violation is reported for a `union` containing a `struct` member.
- 111. (R) Bit-fields shall have type `unsigned int` or `signed int`.
- 112. (R) Bit-fields of type `signed int` shall be at least 2 bits long.
- 113. (R) All `struct/union` members shall be named.
- 114. (R) Reserved and standard library names shall not be redefined.
- 115. (R) Standard library function names shall not be reused.
- x 116. (R) Production libraries shall comply with the MISRA C restrictions.
- x 117. (R) The validity of library function parameters shall be checked.
- 118. (R) Dynamic heap memory allocation shall not be used.
- 119. (R) The error indicator `errno` shall not be used.
- 120. (R) The macro `offsetof` shall not be used.
- 121. (R) `<locale.h>` and the `setlocale` function shall not be used.
- 122. (R) The `setjmp` and `longjmp` functions shall not be used.
- 123. (R) The signal handling facilities of `<signal.h>` shall not be used.
- 124. (R) The `<stdio.h>` library shall not be used in production code.
- 125. (R) The functions `atof/atoi/atol` shall not be used.
- 126. (R) The functions `abort/exit/getenv/system` shall not be used.
- 127. (R) The time handling functions of library `<time.h>` shall not be used.

16.2. MISRA C:2004

This section lists all supported and unsupported MISRA C:2004 rules.

See also [Section 3.6.2, C Code Checking: MISRA C](#).

A number of MISRA C rules leave room for interpretation. Other rules can only be checked in a limited way. In such cases the implementation decisions and possible restrictions for these rules are listed.

x means that the rule is not supported by the TASKING C compiler. (R) is a required rule, (A) is an advisory rule.

Environment

- 1.1 (R) All code shall conform to ISO 9899:1990 "Programming languages - C", amended and corrected by ISO/IEC 9899/COR1:1995, ISO/IEC 9899/AMD1:1995, and ISO/IEC 9899/COR2:1996.
- 1.2 (R) No reliance shall be placed on undefined or unspecified behavior.
- ✘ 1.3 (R) Multiple compilers and/or languages shall only be used if there is a common defined interface standard for object code to which the languages/compilers/assemblers conform.
- ✘ 1.4 (R) The compiler/linker shall be checked to ensure that 31 character significance and case sensitivity are supported for external identifiers.
- ✘ 1.5 (A) Floating-point implementations should comply with a defined floating-point standard.

Language extensions

- 2.1 (R) Assembly language shall be encapsulated and isolated.
- 2.2 (R) Source code shall only use `/* . . . */` style comments.
- 2.3 (R) The character sequence `/*` shall not be used within a comment.
- 2.4 (A) Sections of code should not be "commented out". In general, it is not possible to decide whether a piece of comment is C code that is commented out, or just some pseudo code. Instead, the following heuristics are used to detect possible C code inside a comment: - a line ends with `';`, or - a line starts with `'}`, possibly preceded by white space

Documentation

- ✘ 3.1 (R) All usage of implementation-defined behavior shall be documented.
- ✘ 3.2 (R) The character set and the corresponding encoding shall be documented.
- ✘ 3.3 (A) The implementation of integer division in the chosen compiler should be determined, documented and taken into account.
- 3.4 (R) All uses of the `#pragma` directive shall be documented and explained. This rule is really a documentation issue. The compiler will flag all `#pragma` directives as violations.
- 3.5 (R) The implementation-defined behavior and packing of bit-fields shall be documented if being relied upon.
- ✘ 3.6 (R) All libraries used in production code shall be written to comply with the provisions of this document, and shall have been subject to appropriate validation.

Character sets

- 4.1 (R) Only those escape sequences that are defined in the ISO C standard shall be used.
- 4.2 (R) Trigraphs shall not be used.

Identifiers

- 5.1 (R) Identifiers (internal and external) shall not rely on the significance of more than 31 characters.
- 5.2 (R) Identifiers in an inner scope shall not use the same name as an identifier in an outer scope, and therefore hide that identifier.
- 5.3 (R) A `typedef` name shall be a unique identifier.
- 5.4 (R) A tag name shall be a unique identifier.
- 5.5 (A) No object or function identifier with static storage duration should be reused.
- 5.6 (A) No identifier in one name space should have the same spelling as an identifier in another name space, with the exception of structure and union member names.
- 5.7 (A) No identifier name should be reused.

Types

- 6.1 (R) The plain `char` type shall be used only for storage and use of character values.
- 6.2 (R) `signed` and `unsigned char` type shall be used only for the storage and use of numeric values.
- 6.3 (A) `typedefs` that indicate size and signedness should be used in place of the basic types.
- 6.4 (R) Bit-fields shall only be defined to be of type `unsigned int` or `signed int`.
- 6.5 (R) Bit-fields of type `signed int` shall be at least 2 bits long.

Constants

- 7.1 (R) Octal constants (other than zero) and octal escape sequences shall not be used.

Declarations and definitions

- 8.1 (R) Functions shall have prototype declarations and the prototype shall be visible at both the function definition and call.
- 8.2 (R) Whenever an object or function is declared or defined, its type shall be explicitly stated.
- 8.3 (R) For each function parameter the type given in the declaration and definition shall be identical, and the return types shall also be identical.
- 8.4 (R) If objects or functions are declared more than once their types shall be compatible.
- 8.5 (R) There shall be no definitions of objects or functions in a header file.
- 8.6 (R) Functions shall be declared at file scope.
- 8.7 (R) Objects shall be defined at block scope if they are only accessed from within a single function.
- 8.8 (R) An external object or function shall be declared in one and only one file.

TASKING VX-toolset for MCS User Guide

- 8.9 (R) An identifier with external linkage shall have exactly one external definition.
- x 8.10 (R) All declarations and definitions of objects or functions at file scope shall have internal linkage unless external linkage is required.
- 8.11 (R) The `static` storage class specifier shall be used in definitions and declarations of objects and functions that have internal linkage.
- 8.12 (R) When an array is declared with external linkage, its size shall be stated explicitly or defined implicitly by initialization.

Initialization

- 9.1 (R) All automatic variables shall have been assigned a value before being used. This rule is checked using worst-case assumptions. This means that violations are reported not only for variables that are guaranteed to be uninitialized, but also for variables that are uninitialized on some execution paths.
- 9.2 (R) Braces shall be used to indicate and match the structure in the non-zero initialization of arrays and structures.
- 9.3 (R) In an enumerator list, the "=" construct shall not be used to explicitly initialize members other than the first, unless all items are explicitly initialized.

Arithmetic type conversions

- 10.1 (R) The value of an expression of integer type shall not be implicitly converted to a different underlying type if:
 - a) it is not a conversion to a wider integer type of the same signedness, or
 - b) the expression is complex, or
 - c) the expression is not constant and is a function argument, or
 - d) the expression is not constant and is a return expression.
- 10.2 (R) The value of an expression of floating type shall not be implicitly converted to a different type if:
 - a) it is not a conversion to a wider floating type, or
 - b) the expression is complex, or
 - c) the expression is a function argument, or
 - d) the expression is a return expression.
- 10.3 (R) The value of a complex expression of integer type may only be cast to a type of the same signedness that is no wider than the underlying type of the expression.
- 10.4 (R) The value of a complex expression of floating type may only be cast to a type that is no wider than the underlying type of the expression.
- 10.5 (R) If the bitwise operators `~` and `<<` are applied to an operand of underlying type `unsigned char` or `unsigned short`, the result shall be immediately cast to the underlying type of the operand.
- 10.6 (R) A "U" suffix shall be applied to all constants of `unsigned` type.

Pointer type conversions

- 11.1 (R) Conversions shall not be performed between a pointer to a function and any type other than an integral type.
- 11.2 (R) Conversions shall not be performed between a pointer to object and any type other than an integral type, another pointer to object type or a pointer to void.
- 11.3 (A) A cast should not be performed between a pointer type and an integral type.
- 11.4 (A) A cast should not be performed between a pointer to object type and a different pointer to object type.
- 11.5 (R) A cast shall not be performed that removes any `const` or `volatile` qualification from the type addressed by a pointer.

Expressions

- 12.1 (A) Limited dependence should be placed on C's operator precedence rules in expressions.
- 12.2 (R) The value of an expression shall be the same under any order of evaluation that the standard permits. This rule is checked using worst-case assumptions. This means that a violation will be reported when a possible alias may cause the result of an expression to be evaluation order dependent.
- 12.3 (R) The `sizeof` operator shall not be used on expressions that contain side effects.
- 12.4 (R) The right-hand operand of a logical `&&` or `||` operator shall not contain side effects.
- 12.5 (R) The operands of a logical `&&` or `||` shall be *primary-expressions*.
- 12.6 (A) The operands of logical operators (`&&`, `||` and `!`) should be effectively Boolean. Expressions that are effectively Boolean should not be used as operands to operators other than (`&&`, `||` and `!`).
- 12.7 (R) Bitwise operators shall not be applied to operands whose underlying type is signed.
- 12.8 (R) The right-hand operand of a shift operator shall lie between zero and one less than the width in bits of the underlying type of the left-hand operand. This violation will only be checked when the shift count evaluates to a constant value at compile time.
- 12.9 (R) The unary minus operator shall not be applied to an expression whose underlying type is unsigned.
- 12.10 (R) The comma operator shall not be used.
- 12.11 (A) Evaluation of constant unsigned integer expressions should not lead to wrap-around.
- 12.12 (R) The underlying bit representations of floating-point values shall not be used. A violation is reported when a pointer to a floating-point type is converted to a pointer to an integer type.
- 12.13 (A) The increment (`++`) and decrement (`--`) operators should not be mixed with other operators in an expression.

Control statement expressions

- 13.1 (R) Assignment operators shall not be used in expressions that yield a Boolean value.

TASKING VX-toolset for MCS User Guide

- 13.2 (A) Tests of a value against zero should be made explicit, unless the operand is effectively Boolean.
- 13.3 (R) Floating-point expressions shall not be tested for equality or inequality.
- 13.4 (R) The controlling expression of a `for` statement shall not contain any objects of floating type.
- 13.5 (R) The three expressions of a `for` statement shall be concerned only with loop control. A violation is reported when the loop initialization or loop update expression modifies an object that is not referenced in the loop test.
- 13.6 (R) Numeric variables being used within a `for` loop for iteration counting shall not be modified in the body of the loop.
- 13.7 (R) Boolean operations whose results are invariant shall not be permitted.

Control flow

- 14.1 (R) There shall be no unreachable code.
- 14.2 (R) All non-null statements shall either:
 - a) have at least one side effect however executed, or
 - b) cause control flow to change.
- 14.3 (R) Before preprocessing, a null statement shall only occur on a line by itself; it may be followed by a comment provided that the first character following the null statement is a white-space character.
- 14.4 (R) The `goto` statement shall not be used.
- 14.5 (R) The `continue` statement shall not be used.
- 14.6 (R) For any iteration statement there shall be at most one `break` statement used for loop termination.
- 14.7 (R) A function shall have a single point of exit at the end of the function.
- 14.8 (R) The statement forming the body of a `switch`, `while`, `do ... while` or `for` statement be a compound statement.
- 14.9 (R) An `if (expression)` construct shall be followed by a compound statement. The `else` keyword shall be followed by either a compound statement, or another `if` statement.
- 14.10 (R) All `if ... else if` constructs shall be terminated with an `else` clause.

Switch statements

- 15.1 (R) A switch label shall only be used when the most closely-enclosing compound statement is the body of a `switch` statement.
- 15.2 (R) An unconditional `break` statement shall terminate every non-empty `switch` clause.
- 15.3 (R) The final clause of a `switch` statement shall be the `default` clause.
- 15.4 (R) A `switch` expression shall not represent a value that is effectively Boolean.
- 15.5 (R) Every `switch` statement shall have at least one `case` clause.

Functions

- 16.1 (R) Functions shall not be defined with variable numbers of arguments.
- 16.2 (R) Functions shall not call themselves, either directly or indirectly. A violation will be reported for direct or indirect recursive function calls in the source file being checked. Recursion via functions in other source files, or recursion via function pointers is not detected.
- 16.3 (R) Identifiers shall be given for all of the parameters in a function prototype declaration.
- 16.4 (R) The identifiers used in the declaration and definition of a function shall be identical.
- 16.5 (R) Functions with no parameters shall be declared with parameter type `void`.
- 16.6 (R) The number of arguments passed to a function shall match the number of parameters.
- 16.7 (A) A pointer parameter in a function prototype should be declared as pointer to `const` if the pointer is not used to modify the addressed object.
- 16.8 (R) All exit paths from a function with non-void return type shall have an explicit `return` statement with an expression.
- 16.9 (R) A function identifier shall only be used with either a preceding `&`, or with a parenthesized parameter list, which may be empty.
- 16.10 (R) If a function returns error information, then that error information shall be tested. A violation is reported when the return value of a function is ignored.

Pointers and arrays

- x 17.1 (R) Pointer arithmetic shall only be applied to pointers that address an array or array element.
- x 17.2 (R) Pointer subtraction shall only be applied to pointers that address elements of the same array.
- 17.3 (R) `>`, `>=`, `<`, `<=` shall not be applied to pointer types except where they point to the same array. In general, checking whether two pointers point to the same object is impossible. The compiler will only report a violation for a relational operation with incompatible pointer types.
- 17.4 (R) Array indexing shall be the only allowed form of pointer arithmetic.
- 17.5 (A) The declaration of objects should contain no more than 2 levels of pointer indirection. A violation is reported when a pointer with three or more levels of indirection is declared.
- 17.6 (R) The address of an object with automatic storage shall not be assigned to another object that may persist after the first object has ceased to exist.

Structures and unions

- 18.1 (R) All structure or union types shall be complete at the end of a translation unit.
- 18.2 (R) An object shall not be assigned to an overlapping object.
- x 18.3 (R) An area of memory shall not be reused for unrelated purposes.

18.4 (R) Unions shall not be used.

Preprocessing directives

19.1 (A) `#include` statements in a file should only be preceded by other preprocessor directives or comments.

19.2 (A) Non-standard characters should not occur in header file names in `#include` directives.

x 19.3 (R) The `#include` directive shall be followed by either a `<filename>` or "filename" sequence.

19.4 (R) C macros shall only expand to a braced initializer, a constant, a parenthesized expression, a type qualifier, a storage class specifier, or a do-while-zero construct.

19.5 (R) Macros shall not be `#define'd` or `#undef'd` within a block.

19.6 (R) `#undef` shall not be used.

19.7 (A) A function should be used in preference to a function-like macro.

19.8 (R) A function-like macro shall not be invoked without all of its arguments.

19.9 (R) Arguments to a function-like macro shall not contain tokens that look like preprocessing directives. A violation is reported when the first token of an actual macro argument is '#'.

19.10 (R) In the definition of a function-like macro each instance of a parameter shall be enclosed in parentheses unless it is used as the operand of `#` or `##`.

19.11 (R) All macro identifiers in preprocessor directives shall be defined before use, except in `#ifdef` and `#ifndef` preprocessor directives and the `defined()` operator.

19.12 (R) There shall be at most one occurrence of the `#` or `##` preprocessor operators in a single macro definition.

19.13 (A) The `#` and `##` preprocessor operators should not be used.

19.14 (R) The `defined` preprocessor operator shall only be used in one of the two standard forms.

19.15 (R) Precautions shall be taken in order to prevent the contents of a header file being included twice.

19.16 (R) Preprocessing directives shall be syntactically meaningful even when excluded by the preprocessor.

19.17 (R) All `#else`, `#elif` and `#endif` preprocessor directives shall reside in the same file as the `#if` or `#ifdef` directive to which they are related.

Standard libraries

20.1 (R) Reserved identifiers, macros and functions in the standard library, shall not be defined, redefined or undefined.

20.2 (R) The names of standard library macros, objects and functions shall not be reused.

x 20.3 (R) The validity of values passed to library functions shall be checked.

- 20.4 (R) Dynamic heap memory allocation shall not be used.
- 20.5 (R) The error indicator `errno` shall not be used.
- 20.6 (R) The macro `offsetof`, in library `<stddef.h>`, shall not be used.
- 20.7 (R) The `setjmp` macro and the `longjmp` function shall not be used.
- 20.8 (R) The signal handling facilities of `<signal.h>` shall not be used.
- 20.9 (R) The input/output library `<stdio.h>` shall not be used in production code.
- 20.10 (R) The library functions `atof`, `atoi` and `atol` from library `<stdlib.h>` shall not be used.
- 20.11 (R) The library functions `abort`, `exit`, `getenv` and `system` from library `<stdlib.h>` shall not be used.
- 20.12 (R) The time handling functions of library `<time.h>` shall not be used.

Run-time failures

- × 21.1 (R) Minimization of run-time failures shall be ensured by the use of at least one of:
 - a) static analysis tools/techniques;
 - b) dynamic analysis tools/techniques;
 - c) explicit coding of checks to handle run-time faults.

16.3. MISRA C:2012

This section lists all supported and unsupported MISRA C:2012 rules.

See also [Section 3.6.2, C Code Checking: MISRA C](#).

A number of MISRA C rules leave room for interpretation. Other rules can only be checked in a limited way. In such cases the implementation decisions and possible restrictions for these rules are listed.

× means that the rule is not supported by the TASKING C compiler. (M) is a mandatory rule, (R) is a required rule, (A) is an advisory rule.

A standard C environment

- 1.1 (R) The program shall contain no violations of the standard C syntax and constraints, and shall not exceed the implementation's translation limits.
- 1.2 (A) Language extensions should not be used.
- 1.3 (R) There shall be no occurrence of undefined or critical unspecified behavior.

Unused code

- 2.1 (R) A project shall not contain unreachable code.
- 2.2 (R) There shall be no dead code.
- 2.3 (A) A project should not contain unused type declarations.

TASKING VX-toolset for MCS User Guide

- 2.4 (A) A project should not contain unused tag declarations.
- 2.5 (A) A project should not contain unused macro declarations.
- 2.6 (A) A function should not contain unused label declarations.
- 2.7 (A) There should be no unused parameters in functions.

Comments

- 3.1 (R) The character sequences `/*` and `//` shall not be used within a comment.
- 3.2 (R) Line-splicing shall not be used in `//` comments.

Character sets and lexical conventions

- 4.1 (R) Octal and hexadecimal escape sequences shall be terminated.
- 4.2 (A) Trigraphs should not be used.

Identifiers

- 5.1 (R) External identifiers shall be distinct.
- 5.2 (R) Identifiers declared in the same scope and name space shall be distinct.
- 5.3 (R) An identifier declared in an inner scope shall not hide an identifier declared in an outer scope.
- 5.4 (R) Macro identifiers shall be distinct.
- 5.5 (R) Identifiers shall be distinct from macro names.
- 5.6 (R) A `typedef` name shall be a unique identifier.
- 5.7 (R) A tag name shall be a unique identifier.
- 5.8 (R) Identifiers that define objects or functions with external linkage shall be unique.
- 5.9 (A) Identifiers that define objects or functions with internal linkage should be unique.

Types

- 6.1 (R) Bit-fields shall only be declared with an appropriate type.
- 6.2 (R) Single-bit named bit-fields shall not be of a signed type.

Literals and constants

- 7.1 (R) Octal constants shall not be used.
- 7.2 (R) A `"u"` or `"U"` suffix shall be applied to all integer constants that are represented in an `unsigned` type.
- 7.3 (R) The lowercase character `"l"` shall not be used in a literal suffix trivial.
- 7.4 (R) A string literal shall not be assigned to an object unless the object's type is `"pointer to const-qualified char"`.

Declarations and definitions

- 8.1 (R) Types shall be explicitly specified.
- 8.2 (R) Function types shall be in prototype form with named parameters.
- 8.3 (R) All declarations of an object or function shall use the same names and type qualifiers.
- 8.4 (R) A compatible declaration shall be visible when an object or function with external linkage is defined.
- 8.5 (R) An external object or function shall be declared once in one and only one file.
- 8.6 (R) An identifier with external linkage shall have exactly one external definition.
- 8.7 (A) Functions and objects should not be defined with external linkage if they are referenced in only one translation unit.
- 8.8 (R) The `static` storage class specifier shall be used in all declarations of objects and functions that have internal linkage.
- 8.9 (A) An object should be defined at block scope if its identifier only appears in a single function.
- 8.10 (R) An inline function shall be declared with the `static` storage class.
- 8.11 (A) When an array with external linkage is declared, its size should be explicitly specified.
- 8.12 (R) Within an enumerator list, the value of an implicitly-specified enumeration constant shall be unique.
- 8.13 (A) A pointer should point to a `const`-qualified type whenever possible.
- 8.14 (R) The `restrict` type qualifier shall not be used.

Initialization

- 9.1 (M) The value of an object with automatic storage duration shall not be read before it has been set.
- 9.2 (R) The initializer for an aggregate or union shall be enclosed in braces.
- 9.3 (R) Arrays shall not be partially initialized.
- 9.4 (R) An element of an object shall not be initialized more than once.
- 9.5 (R) Where designated initializers are used to initialize an array object the size of the array shall be specified explicitly.

The essential type model

- 10.1 (R) Operands shall not be of an inappropriate essential type.
- 10.2 (R) Expressions of essentially character type shall not be used inappropriately in addition and subtraction operations.
- 10.3 (R) The value of an expression shall not be assigned to an object with a narrower essential type or of a different essential type category.
- 10.4 (R) Both operands of an operator in which the usual arithmetic conversions are performed shall have the same essential type category.

TASKING VX-toolset for MCS User Guide

- 10.5 (A) The value of an expression should not be cast to an inappropriate essential type.
- 10.6 (R) The value of a composite expression shall not be assigned to an object with wider essential type.
- 10.7 (R) If a composite expression is used as one operand of an operator in which the usual arithmetic conversions are performed then the other operand shall not have wider essential type.
- 10.8 (R) The value of a composite expression shall not be cast to a different essential type category or a wider essential type.

Pointer type conversions

- 11.1 (R) Conversions shall not be performed between a pointer to a function and any other type.
- 11.2 (R) Conversions shall not be performed between a pointer to an incomplete type and any other type.
- 11.3 (R) A cast shall not be performed between a pointer to object type and a pointer to a different object type.
- 11.4 (A) A conversion should not be performed between a pointer to object and an integer type.
- 11.5 (A) A conversion should not be performed from pointer to `void` into pointer to object.
- 11.6 (R) A cast shall not be performed between pointer to `void` and an arithmetic type.
- 11.7 (R) A cast shall not be performed between pointer to object and a non-integer arithmetic type.
- 11.8 (R) A cast shall not remove any `const` or `volatile` qualification from the type pointed to by a pointer.
- 11.9 (R) The macro `NULL` shall be the only permitted form of integer null pointer constant.

Expressions

- 12.1 (A) The precedence of operators within expressions should be made explicit.
- 12.2 (R) The right hand operand of a shift operator shall lie in the range zero to one less than the width in bits of the essential type of the left hand operand.
- 12.3 (A) The comma operator should not be used.
- 12.4 (A) Evaluation of constant expressions should not lead to unsigned integer wrap-around.
- 12.5 (M) The `sizeof` operator shall not have an operand which is a function parameter declared as "array of type".

Side effects

- 13.1 (R) Initializer lists shall not contain persistent side effects.
- 13.2 (R) The value of an expression and its persistent side effects shall be the same under all permitted evaluation orders.

- 13.3 (A) A full expression containing an increment (++) or decrement (--) operator should have no other potential side effects other than that caused by the increment or decrement operator.
- 13.4 (A) The result of an assignment operator should not be used.
- 13.5 (R) The right hand operand of a logical && or || operator shall not contain persistent side effects.
- 13.6 (M) The operand of the sizeof operator shall not contain any expression which has potential side effects.

Control statement expressions

- 14.1 (R) A loop counter shall not have essentially floating type.
- 14.2 (R) A for loop shall be well-formed.
- 14.3 (R) Controlling expressions shall not be invariant.
- 14.4 (R) The controlling expression of an if statement and the controlling expression of an iteration-statement shall have essentially Boolean type.

Control flow

- 15.1 (A) The goto statement should not be used.
- 15.2 (R) The goto statement shall jump to a label declared later in the same function.
- 15.3 (R) Any label referenced by a goto statement shall be declared in the same block, or in any block enclosing the goto statement.
- 15.4 (A) There should be no more than one break or goto statement used to terminate any iteration statement.
- 15.5 (A) A function should have a single point of exit at the end.
- 15.6 (R) The body of an iteration-statement or a selection-statement shall be a compound-statement.
- 15.7 (R) All if ... else if constructs shall be terminated with an else statement.

Switch statements

- 16.1 (R) All switch statements shall be well-formed.
- 16.2 (R) A switch label shall only be used when the most closely-enclosing compound statement is the body of a switch statement.
- 16.3 (R) An unconditional break statement shall terminate every switch-clause.
- 16.4 (R) Every switch statement shall have a default label.
- 16.5 (R) A default label shall appear as either the first or the last switch label of a switch statement.
- 16.6 (R) Every switch statement shall have at least two switch-clauses.
- 16.7 (R) A switch-expression shall not have essentially Boolean type.

Functions

- 17.1 (R) The features of `<stdarg.h>` shall not be used.
- 17.2 (R) Functions shall not call themselves, either directly or indirectly.
- 17.3 (M) A function shall not be declared implicitly.
- 17.4 (M) All exit paths from a function with non-void return type shall have an explicit `return` statement with an expression.
- 17.5 (A) The function argument corresponding to a parameter declared to have an array type shall have an appropriate number of elements.
- 17.6 (M) The declaration of an array parameter shall not contain the `static` keyword between the `[]`.
- 17.7 (R) The value returned by a function having non-void return type shall be used.
- 17.8 (A) A function parameter should not be modified.

Pointers and arrays

- 18.1 (R) A pointer resulting from arithmetic on a pointer operand shall address an element of the same array as that pointer operand.
- 18.2 (R) Subtraction between pointers shall only be applied to pointers that address elements of the same array.
- 18.3 (R) The relational operators `>`, `>=`, `<` and `<=` shall not be applied to objects of pointer type except where they point into the same object.
- 18.4 (A) The `+`, `-`, `+=` and `-=` operators should not be applied to an expression of pointer type.
- 18.5 (A) Declarations should contain no more than two levels of pointer nesting.
- 18.6 (R) The address of an object with automatic storage shall not be copied to another object that persists after the first object has ceased to exist.
- 18.7 (R) Flexible array members shall not be declared.
- 18.8 (R) Variable-length array types shall not be used.

Overlapping storage

- 19.1 (M) An object shall not be assigned or copied to an overlapping object.
- 19.2 (A) The `union` keyword should not be used.

Preprocessing directives

- 20.1 (A) `#include` directives should only be preceded by preprocessor directives or comments.
- 20.2 (R) The `'`, `"` or `\` characters and the `/*` or `//` character sequences shall not occur in a header file name.
- 20.3 (R) The `#include` directive shall be followed by either a `<filename>` or `"filename"` sequence.

- 20.4 (R) A macro shall not be defined with the same name as a keyword.
- 20.5 (A) `#undef` should not be used.
- 20.6 (R) Tokens that look like a preprocessing directive shall not occur within a macro argument
- 20.7 (R) Expressions resulting from the expansion of macro parameters shall be enclosed in parentheses.
- 20.8 (R) The controlling expression of a `#if` or `#elif` preprocessing directive shall evaluate to 0 or 1.
- 20.9 (R) All identifiers used in the controlling expression of `#if` or `#elif` preprocessing directives shall be `#define`'d before evaluation.
- 20.10 (A) The `#` and `##` preprocessor operators should not be used.
- 20.11 (R) A macro parameter immediately following a `#` operator shall not immediately be followed by a `##` operator.
- 20.12 (R) A macro parameter used as an operand to the `#` or `##` operators, which is itself subject to further macro replacement, shall only be used as an operand to these operators.
- 20.13 (R) A line whose first token is `#` shall be a valid preprocessing directive.
- 20.14 (R) All `#else`, `#elif` and `#endif` preprocessor directives shall reside in the same file as the `#if`, `#ifdef` or `#ifndef` directive to which they are related.

Standard libraries

- 21.1 (R) `#define` and `#undef` shall not be used on a reserved identifier or reserved macro name.
- 21.2 (R) A reserved identifier or macro name shall not be declared.
- 21.3 (R) The memory allocation and deallocation functions of `<stdlib.h>` shall not be used.
- 21.4 (R) The standard header file `<setjmp.h>` shall not be used.
- 21.5 (R) The standard header file `<signal.h>` shall not be used.
- 21.6 (R) The Standard Library input/output functions shall not be used.
- 21.7 (R) The `atoi`, `atol` and `atoll` functions of `<stdlib.h>` shall not be used.
- 21.8 (R) The library functions `abort`, `exit` and `system` of `<stdlib.h>` shall not be used.
- 21.9 (R) The library functions `bsearch` and `qsort` of `<stdlib.h>` shall not be used.
- 21.10 (R) The Standard Library time and date functions shall not be used
- 21.11 (R) The standard header file `<tgmath.h>` shall not be used.
- 21.12 (A) The exception handling features of `<fenv.h>` should not be used.
- 21.13 (M) Any value passed to a function in `<ctype.h>` shall be representable as an `unsigned char` or be the value `EOF`.
- 21.14 (R) The Standard Library function `memcmp` shall not be used to compare null terminated strings.
- 21.15 (R) The pointer arguments to the Standard Library functions `memcpy`, `memmove` and `memcmp` shall be pointers to qualified or unqualified versions of compatible types

TASKING VX-toolset for MCS User Guide

- 21.16 (R) The pointer arguments to the Standard Library function `memcmp` shall point to either a pointer type, an essentially signed type, an essentially unsigned type, an essentially Boolean type or an essentially enum type
- 21.17 (M) Use of the string handling functions from `<string.h>` shall not result in accesses beyond the bounds of the objects referenced by their pointer parameters.
- 21.18 (M) The `size_t` argument passed to any function in `<string.h>` shall have an appropriate value.
- 21.19 (M) The pointers returned by the Standard Library functions `localeconv`, `getenv`, `setlocale` or `strerror` shall only be used as if they have pointer to const-qualified type.
- 21.20 (M) The pointer returned by the Standard Library functions `asctime`, `ctime`, `gmtime`, `localtime`, `localeconv`, `getenv`, `setlocale` or `strerror` shall not be used following a subsequent call to the same function.

Resources

- x 22.1 (R) All resources obtained dynamically by means of Standard Library functions shall be explicitly released.
- x 22.2 (M) A block of memory shall only be freed if it was allocated by means of a Standard Library function.
- x 22.3 (R) The same file shall not be open for read and write access at the same time on different streams.
- x 22.4 (M) There shall be no attempt to write to a stream which has been opened as read-only.
- x 22.5 (M) A pointer to a `FILE` object shall not be dereferenced.
- x 22.6 (M) The value of a pointer to a `FILE` shall not be used after the associated stream has been closed.
- x 22.7 (R) The macro `EOF` shall only be compared with the unmodified return value from any Standard Library function capable of returning `EOF`.
- x 22.8 (R) The value of `errno` shall be set to zero prior to a call to an `errno`-setting-function.
- x 22.9 (R) The value of `errno` shall be tested against zero after calling an `errno`-setting-function.
- x 22.10 (R) The value of `errno` shall only be tested when the last function to be called was an `errno`-setting-function.

Chapter 17. C Implementation-defined Behavior

The TASKING VX-toolset for MCS C compiler fully supports the ISO-C standard, but some parts of the ISO-C standard are implementation-defined. This chapter describes how the implementation-defined areas and the locale-specific areas of the C language are implemented in the TASKING C compiler for ISO C99 and ISO C11. Below are some remarks on the other behaviors as mentioned in the standard.

Unspecified behavior

Unspecified behavior is the use of an unspecified value, or other behavior where the ISO-C standard provides two or more possibilities and imposes no further requirements on which is chosen in any instance. Some of the unspecified behaviors are relevant to users of the TASKING VX-toolset for MCS. Some unspecified behaviors are specified in the EABI. The silicon vendor is responsible for the EABI.

Undefined behavior

Undefined behavior is behavior, upon use of a non-portable or erroneous program construct or of erroneous data, for which the ISO-C standard imposes no requirements.

Some undefined behaviors may trigger a compiler error or warning. Altium does not provide any guarantees about whether or not the compiler issues an error or warning. It is important to know whether your software contains undefined behaviors since this will make the source non-portable between compiler vendors and between other processors.

The MISRA C and CERT coding guides do not refer to undefined behaviors explicitly.

17.1. C99 Implementation-defined Behavior

Implementation-defined behavior is unspecified behavior where each implementation documents how the choice is made.

The following sections describe the implementation-defined characteristics. The section numbers listed in parenthesis refer to the corresponding sections in the ISO C99 standard. The order in this chapter is the same as used in Annex J.3 of the ISO/IEC 9899:1999 (E) standard.

17.1.1. Translation

- How a diagnostic is identified (3.10, 5.1.1.3).

The C compiler diagnostics are explained in [Section 3.7, C Compiler Error Messages](#).

- Whether each nonempty sequence of white-space characters other than new-line is retained or replaced by one space character in translation phase 3 (5.1.1.2).

White-space is retained.

17.1.2. Environment

- The mapping between physical source file multibyte characters and the source character set in translation phase 1 (5.1.1.2).

Use of variable length encoded characters in the source file in comments and string literals is permitted. A one-on-one mapping is done without interpretation of multibyte characters.

- The name and type of the function called at program startup in a freestanding environment (5.1.2.1).

The function called at program startup (in `cstart.c`) is called `main`. The prototype for `main` in `cstart.c` is:

```
extern int main( int argc, char *argv[] );
```

- The effect of program termination in a freestanding environment (5.1.2.1).

Execution is halted if the program is executed under control of a debugger, otherwise the program will loop forever in function `_Exit()`.

- An alternative manner in which the `main` function may be defined (5.1.2.2.1).

You can change the definition of `main` by altering file `cstart.c`.

- The values given to the strings pointed to by the `argv` argument to `main` (5.1.2.2.1).

The strings get their values from the arguments given in file `cstart.c`. The program arguments are treated case sensitive.

- What constitutes an interactive device (5.1.2.3).

The streams `stdin`, `stdout` and `stderr` are treated as interactive devices. The debugger uses these streams with File System Simulation (FSS) windows to interact.

- The set of signals, their semantics, and their default handling (7.14).

The signals are described in [Section 10.1.17, `signal.h`](#).

- Signal values other than `SIGFPE`, `SIGILL`, and `SIGSEGV` that correspond to a computational exception (7.14.1.1).

There are no other values that correspond to a computational exception. All signal values are described in [Section 10.1.17, `signal.h`](#).

- Signals for which the equivalent of `signal(sig, SIG_IGN);` is executed at program startup (7.14.1.1).

By default the implementation does not ignore any signals at program startup.

- The set of environment names and the method for altering the environment list used by the `getenv` function (7.20.4.5).

There are no implementation-defined environment names that are used by the `getenv` function. A skeleton is provided for the `getenv` function in the C library, because the embedded environment has no operating system. The `getenv` function calls the name as a `void` function.

- The manner of execution of the string by the `system` function (7.20.4.6).

A skeleton is provided for the `system()` function in the C library, because the embedded environment has no operating system. The `system()` function calls the string as a `void` function.

17.1.3. Identifiers

- Which additional multibyte characters may appear in identifiers and their correspondence to universal character names (6.4.2).

No additional multibyte characters are supported in an identifier.

- The number of significant initial characters in an identifier (5.2.4.1, 6.4.2).

All characters in an identifier are significant.

17.1.4. Characters

- The number of bits in a byte (3.6).

There are 24 bits in a byte.

- The values of the members of the execution character set (5.2.1).

Only 24-bit characters are supported. The values of the execution character set are the same as that of the source character set. The same representation value is used for each member in the characters sets except for the escape sequences.

- The unique value of the member of the execution character set produced for each of the standard alphabetic escape sequences (5.2.2).

The following table contains an overview of the escape sequences and their byte value in the execution character set.

Escape sequence	Value
<code>\a</code>	7
<code>\b</code>	8
<code>\f</code>	12
<code>\n</code>	10
<code>\r</code>	13
<code>\t</code>	9

Escape sequence	Value
<code>\v</code>	11

- The value of a `char` object into which has been stored any character other than a member of the basic execution character set (6.2.5).

Any 24-bit value can be stored in a `char` object.

- Which of `signed char` or `unsigned char` has the same range, representation, and behavior as "plain" `char` (6.2.5, 6.3.1.1).

By default "plain" `char` is the same as specifying `signed char`. With C compiler option `--uchar (-u)` you can change the default to `unsigned char`.

- The mapping of members of the source character set (in character constants and string literals) to members of the execution character set (6.4.4.4, 5.1.1.2).

The mapping is one-to-one. The values of the execution character set are the same as that of the source character set. The same representation value is used for each member in the characters sets except for the escape sequences.

- The value of an integer character constant containing more than one character or containing a character or escape sequence that does not map to a single-byte execution character (6.4.4.4).

For any character constant containing more than one character, a warning is issued and the value is truncated to type `signed char`.

- The value of a wide character constant containing more than one multibyte character, or containing a multibyte character or escape sequence not represented in the extended execution character set (6.4.4.4).

A wide character constant can contain at most one multibyte character. Its value is represented in an `unsigned short int`. A number of wide character functions are available as C source code, but have not been compiled with the C library. To use complete wide character functionality, you must recompile the libraries with the macro `WCHAR_SUPPORT_ENABLED` and keep this macro also defined when compiling your own sources.

- The current locale used to convert a wide character constant consisting of a single multibyte character that maps to a member of the extended execution character set into a corresponding wide character code (6.4.4.4).

By default, the "C" locale is used.

- The current locale used to convert a wide string literal into corresponding wide character codes (6.4.5).

By default, the "C" locale is used.

- The value of a string literal containing a multibyte character or escape sequence not represented in the execution character set (6.4.5).

All source characters can be represented in the execution character set.

17.1.5. Integers

- Any extended integer types that exist in the implementation (6.2.5).

All types are described in [Section 1.1, Data Types](#).

- Whether signed integer types are represented using sign and magnitude, two's complement, or one's complement, and whether the extraordinary value is a trap representation or an ordinary value (6.2.6.2).

Signed integer types are represented in two's complement. The most significant bit is the sign bit. 1 is negative, 0 is positive.

- The rank of any extended integer type relative to another extended integer type with the same precision (6.3.1.1).

All types are described in [Section 1.1, Data Types](#).

- The result of, or the signal raised by, converting an integer to a signed integer type when the value cannot be represented in an object of that type (6.3.1.3).

At compile time, when converting integer types and a value does not fit in a type, the compiler issues a warning and the value is truncated. At run-time no warning or signal is given and the value is truncated.

- The results of some bitwise operations on signed integers (6.5).

The result of $E1 \gg E2$ is $E1$ right shifted $E2$ bit positions. If $E1$ has a signed type and a negative value, the shift behavior is implemented as an arithmetic shift. The empty position in the most significant bit is filled with a copy of the original most significant bit.

17.1.6. Floating-Point

- The accuracy of the floating-point operations and of the library functions in `<math.h>` and `<complex.h>` that return floating-point results (5.2.4.2.2).

A float has 24 significant mantissa bits and 8 exponent bits. A double or long double has 53 significant mantissa bits and 11 exponent bits. This is conform IEEE-754 for single precision and double precision floating-point. Internally the compiler uses a mantissa of 80 bits. The results of floating-point operations are rounded to the nearest IEEE-754 format.

The accuracy of `sqrt` is defined unknown.

- The rounding behaviors characterized by non-standard values of `FLT_ROUNDS` (5.2.4.2.2).

No non-standard values are used.

- The evaluation methods characterized by non-standard negative values of `FLT_EVAL_METHOD` (5.2.4.2.2).

`FLT_EVAL_METHOD` is defined as 0. No non-standard values are used.

TASKING VX-toolset for MCS User Guide

- The direction of rounding when an integer is converted to a floating-point number that cannot exactly represent the original value (6.3.1.4).

The round to nearest method is used. `FLT_ROUND`s is ignored.

- The direction of rounding when a floating-point number is converted to a narrower floating-point number (6.3.1.5).

The round to nearest method is used. `FLT_ROUND`s is ignored.

- How the nearest representable value or the larger or smaller representable value immediately adjacent to the nearest representable value is chosen for certain floating constants (6.4.4.2).

The round to nearest method is used. `FLT_ROUND`s is ignored.

- Whether and how floating expressions are contracted when not disallowed by the `FP_CONTRACT` pragma (6.5).

Pragma `FP_CONTRACT` is equivalent to [compiler option `--fp-model=+contract`](#). This has only effect for fused multiply-and-accumulate (FMA) operations. FMA operations are not supported by the IEEE 754-1985 standard. The result of FMA operations is only rounded once at the end of the FMA. You can disable FMAs with the [compiler option `--fp-model=-contract`](#).

- The default state for the `FENV_ACCESS` pragma (7.6.1).

The default state of pragma `FENV_ACCESS` is "off". This pragma is ignored.

- Additional floating-point exceptions, rounding modes, environments, and classifications, and their macro names (7.6, 7.12).

No additional floating-point exceptions, rounding modes, environments, and classifications are defined.

- The default state for the `FP_CONTRACT` pragma (7.12.2).

The default state of pragma `FP_CONTRACT` is set by the **contract** flag of [compiler option `--fp-model`](#). The default state is "on".

- Whether the "inexact" floating-point exception can be raised when the rounded result actually does equal the mathematical result in an IEC 60559 conformant implementation (F.9).

The "inexact" floating-point exception is not supported.

- Whether the "underflow" (and "inexact") floating-point exception can be raised when a result is tiny but not inexact in an IEC 60559 conformant implementation (F.9).

The "underflow" and "inexact" floating-point exceptions are not supported.

17.1.7. Arrays and Pointers

- The result of converting a pointer to an integer or vice versa (6.3.2.3).

All non-pointer conversions to and from a 24-bit pointer are implemented as a conversion to or from a 24-bit integer type.

- The size of the result of subtracting two pointers to elements of the same array (6.5.6).

The size of `ptrdiff_t` is 24 bits. The difference in address location is expressed in bytes.

17.1.8. Hints

- The extent to which suggestions made by using the `register` storage-class specifier are effective (6.7.1).

The compiler does not make assumptions based on the `register` storage-class specifier. So, basically this keyword is ignored, except that you cannot take the address of a `register` variable. The compiler issues an error in that case.

- The extent to which suggestions made by using the `inline` function specifier are effective (6.7.4).

With the `inline` keyword you force the compiler to inline the specified function, regardless of the optimization strategy of the compiler itself. For more information see [Section 1.9.5, Inlining Functions: inline](#).

17.1.9. Structures, Unions, Enumerations, and Bit-fields

- Whether a "plain" `int` bit-field is treated as a `signed int` bit-field or as an `unsigned int` bit-field (6.7.2, 6.7.2.1).

By default an `int` bit-field is treated as `unsigned int`. This offers the best performance. With C compiler option **--signed-bitfields** you tell the compiler to treat `int` bit-fields as `signed int`. In this case, you can still add the keyword `unsigned` to treat a particular `int` bit-field as `unsigned`.

- Allowable bit-field types other than `_Bool`, `signed int`, and `unsigned int` (6.7.2.1).

The integer types `signed char`, `unsigned char`, `signed short` and `unsigned short` as specified in [Section 1.1, Data Types](#), are also allowable bit-field types.

- Whether a bit-field can straddle a storage-unit boundary (6.7.2.1).

A bit-field cannot straddle a storage-unit boundary. If insufficient space remains, the bit-field is put into the next unit.

- The order of allocation of bit-fields within a unit (6.7.2.1).

Allocation starts at the least significant bit up to the most significant bit. If the following bit-field fits within the same unit, it is allocated starting at the next available bit.

- The alignment of non-bit-field members of structures (6.7.2.1). This should present no problem unless binary data written by one implementation is read by another.

The alignment of non-bit-field members of structures is the same as the alignment for data types as specified in [Section 1.1, Data Types](#).

- The integer type compatible with each enumerated type (6.7.2.2).

The compiler always uses `int` for enumeration.

17.1.10. Qualifiers

- What constitutes an access to an object that has `volatile`-qualified type (6.7.3).

Any reference to an object with `volatile` type results in an access. The order in which `volatile` objects are accessed is defined by the order expressed in the source code. References to non-volatile objects are scheduled in arbitrary order, within the constraints given by dependencies.

If the compiler option `--language=+volatile (-Av)` is set, all references to non-volatile objects result in an access before the access to a `volatile` object that occurs subsequently in the source file takes place. The volatile access acts as a memory barrier.

17.1.11. Preprocessing Directives

- How sequences in both forms of header names are mapped to headers or external source file names (6.4.7).

Sequences in header names are mapped to file names as is. The backslash `"\"` is not interpreted as an escape sequence. The backslash `"\"` (Windows) or forward slash `"/` (Windows and UNIX) is interpreted as a standard directory separator.

- Whether the value of a character constant in a constant expression that controls conditional inclusion matches the value of the same character constant in the execution character set (6.10.1).

A character constant in a constant expression that controls conditional inclusion matches the value of the same character constant in the execution character set.

- Whether the value of a single-character character constant in a constant expression that controls conditional inclusion may have a negative value (6.10.1).

A single-character character constant in a constant expression that controls conditional inclusion may have a negative value.

- The places that are searched for an included `< >` delimited header, and how the places are specified or the header is identified (6.10.2).

How the compiler searches for include files is explained in [Section 3.3, *How the Compiler Searches Include Files*](#).

- How the named source file is searched for in an included `" "` delimited header (6.10.2).

How the compiler searches for include files is explained in [Section 3.3, *How the Compiler Searches Include Files*](#).

- The method by which preprocessing tokens (possibly resulting from macro expansion) in a `#include` directive are combined into a header name (6.10.2).

Preprocessing tokens in a `#include` directive are combined the same way as outside a `#include` directive.

- The nesting limit for `#include` processing (6.10.2).

There is no nesting limit for `#include` processing.

- Whether the `#` operator inserts a `\` character before the `\` character that begins a universal character name in a character constant or string literal (6.10.3.2).

The `#` operator inserts a `\` character before every `\` character in a character constant or string literal.

- The behavior on each recognized non-STDC `#pragma` directive (6.10.6).

All non-STDC pragmas are described in [Section 1.7, *Pragmas to Control the Compiler*](#).

- The definitions for `__DATE__` and `__TIME__` when respectively, the date and time of translation are not available (6.10.8).

The date and time of translation are always available, macros `__DATE__` and `__TIME__` are always defined.

17.1.12. Library Functions

- Any library facilities available to a freestanding program, other than the minimal set required by clause 4 (5.1.2.1).

All library functions are described in [Chapter 10, *Libraries*](#). Some functions are not completely implemented because their implementation depends on the context where your application will run. These functions are for example all I/O related functions. Where possible, these functions are implemented using file system simulation (FSS). This system can be used by the debugger to simulate an I/O environment which enables you to debug your application. If the application runs under control of the debugger and FSS is used, then the low-level behavior is equal to the host system's file access behavior.

In the implementation in the C library, the basic sequences of a multibyte character consist of single bytes (`MB_LEN_MAX` is set to 1). If you want full multibyte support, you need to change the C library. See the notes in the header files `stdio.h` and `wchar.h` for more information.

- The format of the diagnostic printed by the `assert` macro (7.2.1.1).

The `assert()` function is implemented as a macro in `assert.h`. The output is:

```
Assertion failed: (expression) file filename, line linenumber
```

when the parameter evaluates to zero.

- The representation of the floating-point status flags stored by the `fegetexceptflag` function (7.6.2.2).

Exception flags are supported and are defined in header file `fenv.h`:

```
#define FE_DIVBYZERO    (1 << 1)
#define FE_INEXACT      (1 << 2)
#define FE_INVALID     (1 << 3)
```

TASKING VX-toolset for MCS User Guide

```
#define FE_OVERFLOW    (1 << 4)
#define FE_UNDERFLOW  (1 << 5)
```

- Whether the `feraiseexcept` function raises the "inexact" floating-point exception in addition to the "overflow" or "underflow" floating-point exception (7.6.2.3).

Function `feraiseexcept` does not raise `FE_INEXACT` if underflow or overflow is raised.

- Strings other than "C" and "" that may be passed as the second argument to the `setlocale` function (7.11.1.1).

No other strings are predefined. A NULL pointer as the second argument returns the "C" locale. Any other string than "C" or "" can be passed as the second argument to the `setlocale` function and results in NULL.

- The types defined for `float_t` and `double_t` when the value of the `FLT_EVAL_METHOD` macro is less than 0 or greater than 2 (7.12).

The `FLT_EVAL_METHOD` macro can only have the values 0, 1 or 2.

- Domain errors for the mathematical functions, other than those required by this International Standard (7.12.1).

No other domain errors exist, other than those required by the standard.

- The values returned by the mathematical functions on domain errors (7.12.1).

On domain errors (`errno` is set to `EDOM`), the mathematical functions return a value as specified in the following table.

Math function	Return value on EDOM
<code>acos(x > 1.0)</code>	0.0
<code>asin(x > 1.0)</code>	0.0
<code>log(x < 0.0)</code>	-HUGE_VAL
<code>pow(x <= 0.0)</code>	0.0
<code>sqrt(x < 0.0)</code>	-NaN

- The values returned by the mathematical functions on underflow range errors, whether `errno` is set to the value of the macro `ERANGE` when the integer expression `math_errhandling & MATH_ERRNO` is nonzero, and whether the "underflow" floating-point exception is raised when the integer expression `math_errhandling & MATH_ERREXCEPT` is nonzero. (7.12.1).

On underflow range errors, the mathematical functions return 0.0. `math_errhandling` is set to `MATH_ERRNO`. `errno` is not set to `ERANGE` on underflow range errors

- Whether a domain error occurs or zero is returned when an `fmod` function has a second argument of zero (7.12.10.1).

Zero (0.0) is returned when an `fmod` function has a second argument of zero.

- The base-2 logarithm of the modulus used by the `remquo` functions in reducing the quotient (7.12.10.3).

The `remquo` function calculates at least 8 bits of the quotient.

- Whether the equivalent of `signal(sig, SIG_DFL);` is executed prior to the call of a signal handler, and, if not, the blocking of signals that is performed (7.14.1.1).

The equivalent of `signal(sig, SIG_DFL);` is executed prior to the call of a signal handler.

- The null pointer constant to which the macro `NULL` expands (7.17).

Macro `NULL` is defined as `(void *) 0`.

- Whether the last line of a text stream requires a terminating new-line character (7.19.2).

Both a new-line character (`\n`) and end-of-file (`EOF`) are recognized as the termination character of a line.

- Whether space characters that are written out to a text stream immediately before a new-line character appear when read in (7.19.2).

Space characters written to a stream immediately before a new-line character are preserved.

- The number of null characters that may be appended to data written to a binary stream (7.19.2).

I/O related functions are implemented using file system simulation (FSS). This system can be used by the debugger to simulate an I/O environment. If the application runs under control of the debugger and FSS is used, then the low-level behavior is equal to the host system's file access behavior. The library does not append any null characters. It depends on the `open()` function on the host environment what happens. You can write your own `_open()` function if necessary.

- Whether the file position indicator of an append-mode stream is initially positioned at the beginning or end of the file (7.19.3).

I/O related functions are implemented using file system simulation (FSS). This system can be used by the debugger to simulate an I/O environment. If the application runs under control of the debugger and FSS is used, then the low-level behavior is equal to the host system's file access behavior. Where the file position indicator of an append-mode stream is initially positioned depends on the `open()` function on the host environment. You can write your own `_open()` function if necessary.

- Whether a write on a text stream causes the associated file to be truncated beyond that point (7.19.3).

I/O related functions are implemented using file system simulation (FSS). This system can be used by the debugger to simulate an I/O environment. If the application runs under control of the debugger and FSS is used, then the low-level behavior is equal to the host system's file access behavior. Whether a write on a text stream causes the associated file to be truncated beyond that point depends on how the low-level file routines are implemented in your application.

TASKING VX-toolset for MCS User Guide

- The characteristics of file buffering (7.19.3).

Files can be unbuffered, fully buffered or line buffered. What actually happens depends on how the low-level file routines are implemented in your application.

- Whether a zero-length file actually exists (7.19.3).

This depends on how the low-level file routines are implemented in your application.

- The rules for composing valid file names (7.19.3).

This depends on how the low-level file routines are implemented in your application.

- Whether the same file can be simultaneously open multiple times (7.19.3).

This depends on how the low-level file routines are implemented in your application.

- The nature and choice of encodings used for multibyte characters in files (7.19.3).

Use of variable length encoded characters in files in comments and string literals is permitted.

- The effect of the `remove` function on an open file (7.19.4.1).

This depends on how the low-level file routines are implemented in your application.

- The effect if a file with the new name exists prior to a call to the `rename` function (7.19.4.2).

This depends on how the low-level file routines are implemented in your application.

- Whether an open temporary file is removed upon abnormal program termination (7.19.4.3).

This depends on how the low-level file routines are implemented in your application.

- Which changes of mode are permitted (if any), and under what circumstances (7.19.5.4).

The `freopen()` function first calls `fclose()` and then calls `_fopen()` with the new mode.

- The style used to print an infinity or NaN, and the meaning of any `n-char` or `n-wchar` sequence printed for a NaN (7.19.6.1, 7.24.2.1).

The style used to print an infinity or NaN is `inf` and `nan` respectively (`INF` or `NAN` for the `F` conversion specifier). `n-char` or `n-wchar` sequences are not used for `nan`.

- The output for `%p` conversion in the `fprintf` or `fwprintf` function (7.19.6.1, 7.24.2.1).

The argument is treated as having type `void *`. The value will be printed as a hexadecimal value, similar to `%x`.

- The interpretation of a `-` character that is neither the first nor the last character, nor the second where a `^` character is the first, in the scanlist for `%[` conversion in the `fscanf` or `fwscanf` function (7.19.6.2, 7.24.2.1).

A `-` character is treated as a normal character.

- The set of sequences matched by a `%p` conversion and the interpretation of the corresponding input item in the `fscanf` or `fwscanf` function (7.19.6.2, 7.24.2.2).

The format of `%p` matches the format of `%x`. The input for `%p` is a hexadecimal value, which is converted to a value with type `void *`.

- The value to which the macro `errno` is set by the `fgetpos`, `fsetpos`, or `ftell` functions on failure (7.19.9.1, 7.19.9.3, 7.19.9.4).

If `errno` is set to a value depends on how the low-level file routines are implemented in your application.

- The meaning of any `n-char` or `n-wchar` sequence in a string representing a NaN that is converted by the `strtod`, `strtof`, `strtold`, `wctod`, `wctof`, or `wctold` function (7.20.1.3, 7.24.4.1.1).

An `n-char` or `n-wchar` sequence in a string representing a NaN is ignored.

- Whether or not the `strtod`, `strtof`, `strtold`, `wctod`, `wctof`, or `wctold` function sets `errno` to `ERANGE` when underflow occurs (7.20.1.3, 7.24.4.1.1).

`errno` is set to `ERANGE` when underflow occurs and the value returned is 0.0.

- Whether the `calloc`, `malloc`, and `realloc` functions return a null pointer or a pointer to an allocated object when the size requested is zero (7.20.3).

`NULL` is returned when a size of zero is requested.

- Whether open streams with unwritten buffered data are flushed, open streams are closed, or temporary files are removed when the `abort` or `_Exit` function is called (7.20.4.1, 7.20.4.4).

When the `abort()` or `_Exit()` function is called, open streams with unwritten buffered data are not flushed, open streams are not closed, and temporary files are not removed.

- The termination status returned to the host environment by the `abort`, `exit`, or `_Exit` function (7.20.4.1, 7.20.4.3, 7.20.4.4).

`exit()` and `_Exit()` use the input value as termination status. `abort()` calls `_Exit()` with `EXIT_FAILURE`.

- The value returned by the `system` function when its argument is not a null pointer (7.20.4.6).

A skeleton is provided for the `system()` function in the C library, because the embedded environment has no operating system. The `system()` function returns the value 0.

- The local time zone and Daylight Saving Time (7.23.1).

The default time zone is UTC. Daylight Saving Time is not available (`tm_isdst=-1`).

- The range and precision of times representable in `clock_t` and `time_t` (7.23).

`clock_t` is defined as `unsigned long long`, `time_t` is defined as `unsigned long`. The resolution of the clock is defined by `CLOCKS_PER_SEC`, which is set by means of the C startup code (see the `setclockpersec()` function in `cstart.c`).

TASKING VX-toolset for MCS User Guide

- The era for the `clock` function (7.23.2.1).

The `clock` function returns the current processor time.

- The replacement string for the `%Z` specifier to the `strftime`, and `wcsftime` functions in the "C" locale (7.23.3.5, 7.24.5.1).

`%Z` is replaced by the time zone name, by default UTC.

- Whether or when the trigonometric, hyperbolic, base-e exponential, base-e logarithmic, error, and log gamma functions raise the "inexact" floating-point exception in an IEC 60559 conformant implementation (F.9).

The "inexact" floating-point exception is not supported.

- Whether the functions in `<math.h>` honor the rounding direction mode in an IEC 60559 conformant implementation (F.9).

The round to nearest method is used. `FLT_ROUNDS` is defined as 1.

17.1.13. Architecture

- The values or expressions assigned to the macros specified in the headers `<float.h>`, `<limits.h>`, and `<stdint.h>` (5.2.4.2, 7.18.2, 7.18.3).

Macros in `<float.h>`:

Macro <code><float.h></code>	Value
<code>FLT_RADIX</code>	2
<code>FLT_ROUNDS</code>	1 (round to nearest)
<code>FLT_EVAL_METHOD</code>	0
<code>FLT_MANT_DIG</code>	24
<code>FLT_DIG</code>	6
<code>FLT_EPSILON</code>	1.19209290E-07F
<code>FLT_MIN</code>	1.17549435E-38F
<code>FLT_MIN_EXP</code>	-125
<code>FLT_MIN_10_EXP</code>	-37
<code>FLT_MAX</code>	3.40282347E+38F
<code>FLT_MAX_EXP</code>	+128
<code>FLT_MAX_10_EXP</code>	+38
<code>[L]DBL_MANT_DIG</code>	53
<code>[L]DBL_DIG</code>	15
<code>[L]DBL_EPSILON</code>	2.2204460492503131E-16
<code>[L]DBL_MIN</code>	2.2250738585072014E-308

Macro <float.h>	Value
[L]DBL_MIN_EXP	-1021
[L]DBL_MIN_10_EXP	-307
[L]DBL_MAX	1.7976931348623157E+308
[L]DBL_MAX_EXP	+1024
[L]DBL_MAX_10_EXP	+308
DECIMAL_DIG	17 (for double FP), 9 (for single FP)

Macros in <limits.h>:

Macro <limits.h>	Value
CHAR_BIT	24
SCHAR_MIN	-SCHAR_MAX-1
SCHAR_MAX	0x7ffffff
UCHAR_MAX	0xfffffU
CHAR_MIN	__CHAR_MIN (min value of 'plain' char)
CHAR_MAX	__CHAR_MAX (max value of 'plain' char)
MB_LEN_MAX	1
SHRT_MIN	-SHRT_MAX-1
SHRT_MAX	0x7ffff
USHRT_MAX	0xfffffU
INT_MIN	-INT_MAX-1
INT_MAX	0x7ffff
UINT_MAX	0xfffffU
LONG_MIN	-LONG_MAX-1
LONG_MAX	0x7fffffffffL
ULONG_MAX	0xfffffffffUL
LLONG_MIN	-LLONG_MAX-1
LLONG_MAX	0x7fffffffffffffLL
ULLONG_MAX	0xfffffffffffffULL

The limit macros in <stdint.h> for exact-width, minimum-width and fastest-width integer types have the same ranges as char, short, int, long and long long. Furthermore the following macros are defined:

Macro <stdint.h>	Value
INTPTR_MIN	INT24_MIN
INTPTR_MAX	INT24_MAX

Macro <stdint.h>	Value
UINTPTR_MAX	UINT24_MAX
INTMAX_MIN	INT72_MIN
INTMAX_MAX	INT72_MAX
UINTMAX_MAX	UINT72_MAX
PTRDIFF_MIN	__PTRDIFF_MIN
PTRDIFF_MAX	__PTRDIFF_MAX
SIG_ATOMIC_MIN	INT24_MIN
SIG_ATOMIC_MAX	INT24_MAX
SIZE_MAX	__SIZE_MAX
WCHAR_MIN	__WCHAR_MIN
WCHAR_MAX	__WCHAR_MAX
WINT_MIN	0
WINT_MAX	UINT24_MAX

- The number, order, and encoding of bytes in any object (when not explicitly specified in this International Standard) (6.2.6.1).

All types are described in [Section 1.1, Data Types](#).

- The value of the result of the `sizeof` operator (6.5.3.4).

The value of the size of the data types is described in [Section 1.1, Data Types](#). Divide the size by 8 because the table lists the size of the data types in bits.

17.2. C99 Locale-specific Behavior

Locale-specific behavior is behavior that depends on local conventions of nationality, culture, and language that each implementation documents.

The following items describe the locale-specific characteristics, as indicated in Appendix J.4 of the ISO/IEC 9899:1999 (E) standard.

- Additional members of the source and execution character sets beyond the basic character set (5.2.1).

The compiler accepts all one-byte characters in the host's default character set. Use of variable length encoded characters in the source file in comments and string literals is permitted.

In the implementation in the C library, the basic sequences of a multibyte character consist of single bytes (`MB_LEN_MAX` is set to 1). If you want full multibyte support, you need to change the C library. See the notes in the header files `stdio.h` and `wchar.h` for more information.

- The presence, meaning, and representation of additional multibyte characters in the execution character set beyond the basic character set (5.2.1.2).

Use of variable length encoded characters in the source file in comments and string literals is permitted.

- The shift states used for the encoding of multibyte characters (5.2.1.2).

A multibyte character must be a single byte when in the initial shift state.

- The direction of writing of successive printing characters (5.2.2).

The direction of writing depends on the application and the display device.

- The decimal-point character (7.1.1).

The default decimal-point character is a '.'.

- The set of printing characters (7.4, 7.25.2).

The set of printing characters are the characters for which the `isprint()` function returns true. Printing characters are characters in the range 32 (space) to 126.

- The set of control characters (7.4, 7.25.2).

The set of control characters are the characters for which the `iscntrl()` function returns true. Control characters are characters in the range 0 to 31 and 127.

- The sets of characters tested for by the `isalpha`, `isblank`, `islower`, `ispunct`, `isspace`, `isupper`, `iswalpha`, `iswblank`, `iswlower`, `iswpunct`, `iswspace`, or `iswupper` functions (7.4.1.2, 7.4.1.3, 7.4.1.7, 7.4.1.9, 7.4.1.10, 7.4.1.11, 7.25.2.1.2, 7.25.2.1.3, 7.25.2.1.7, 7.25.2.1.9, 7.25.2.1.10, 7.25.2.1.11).

The characters tested for are specified in the following table.

Function	Characters tested
<code>isalpha</code>	a-z, A-Z
<code>isblank</code>	' ' (space), '\t' (tab)
<code>islower</code>	a-z
<code>ispunct</code>	!, ", #, \$, %, &, ', (,), *, +, ,, -, ., /, :, ;, <, =, >, ?, @, [, \,], ^, _ , ` , {, , }, ~
<code>isspace</code>	' ' (space), '\t', '\n', '\v', '\f', '\r'
<code>isupper</code>	A-Z

- The native environment (7.11.1.1).

The native environment is the same as the "C" locale.

- Additional subject sequences accepted by the numeric conversion functions (7.20.1, 7.24.4.1).

No additional subject sequences are accepted.

TASKING VX-toolset for MCS User Guide

- The collation sequence of the execution character set (7.21.4.3, 7.24.4.4.2).

Only the "C" locale is supported. The `strcoll()` function is the same as the `strcmp()` function. The `wscoll()` function is the same as the `wscmp()` function.

- The contents of the error message strings set up by the `strerror` function (7.21.6.2).

The error message strings returned by `strerror()` depend on the argument. Typically, the values for the argument come from `errno.h`. For a list of messages see [Section 10.1.5, *errno.h*](#).

- The formats for time and date (7.23.3.5, 7.24.5.1).

English names for months and days are used.

`%c` is replaced by the following date and time representation: `%a %b %e %H:%M:%S %Y`

`%x` is replaced by the following date representation: `%m/%d/%y`

`%X` is replaced by the following time representation: `%H:%M:%S`

- Character mappings that are supported by the `towctrans` function (7.25.1).

The character mappings supported by the `towctrans()` function are defined in `wctype.h: _to_lower` and `_to_upper`.

- Character classifications that are supported by the `iswctype` function (7.25.1).

The character classifications supported by the `iswctype()` function are defined in `wctype.h: _alnum`, `_alpha`, `_cntrl`, `_digit`, `_graph`, `_lower`, `_print`, `_punct`, `_space`, `_upper`, `_xdigit` and `_blank`.

17.3. C11 Implementation-defined Behavior

Implementation-defined behavior is unspecified behavior where each implementation documents how the choice is made.

The following sections describe the implementation-defined characteristics. The section numbers listed in parenthesis refer to the corresponding sections in the ISO C11 standard. The order in this chapter is the same as used in Annex J.3 of the ISO/IEC 9899:2011 (E) standard.

17.3.1. Translation

- How a diagnostic is identified (3.10, 5.1.1.3).

The C compiler diagnostics are explained in [Section 3.7, *C Compiler Error Messages*](#).

- Whether each nonempty sequence of white-space characters other than new-line is retained or replaced by one space character in translation phase 3 (5.1.1.2).

White-space is retained.

17.3.2. Environment

- The mapping between physical source file multibyte characters and the source character set in translation phase 1 (5.1.1.2).

Use of variable length encoded characters in the source file in comments and string literals is permitted. A one-on-one mapping is done without interpretation of multibyte characters.

- The name and type of the function called at program startup in a freestanding environment (5.1.2.1).

The function called at program startup (in `cstart.c`) is called `main`. The prototype for `main` in `cstart.c` is:

```
extern int main( int argc, char *argv[] );
```

- The effect of program termination in a freestanding environment (5.1.2.1).

Execution is halted if the program is executed under control of a debugger, otherwise the program will loop forever in function `_Exit()`.

- An alternative manner in which the `main` function may be defined (5.1.2.2.1).

You can change the definition of `main` by altering file `cstart.c`.

- The values given to the strings pointed to by the `argv` argument to `main` (5.1.2.2.1).

The strings get their values from the arguments given in file `cstart.c`. The program arguments are treated case sensitive.

- What constitutes an interactive device (5.1.2.3).

The streams `stdin`, `stdout` and `stderr` are treated as interactive devices. The debugger uses these streams with File System Simulation (FSS) windows to interact.

- Whether a program can have more than one thread of execution in a freestanding environment (5.1.2.4).

There is only a single thread of execution.

- The set of signals, their semantics, and their default handling (7.14).

The signals are described in [Section 10.1.17, `signal.h`](#).

- Signal values other than `SIGFPE`, `SIGILL`, and `SIGSEGV` that correspond to a computational exception (7.14.1.1).

There are no other values that correspond to a computational exception. All signal values are described in [Section 10.1.17, `signal.h`](#).

- Signals for which the equivalent of `signal(sig, SIG_IGN);` is executed at program startup (7.14.1.1).

By default the implementation does not ignore any signals at program startup.

TASKING VX-toolset for MCS User Guide

- The set of environment names and the method for altering the environment list used by the `getenv` function (7.22.4.5).

There are no implementation-defined environment names that are used by the `getenv` function. A skeleton is provided for the `getenv` function in the C library, because the embedded environment has no operating system. The `getenv` function calls the name as a `void` function.

- The manner of execution of the string by the `system` function (7.22.4.6).

A skeleton is provided for the `system()` function in the C library, because the embedded environment has no operating system. The `system()` function calls the string as a `void` function.

17.3.3. Identifiers

- Which additional multibyte characters may appear in identifiers and their correspondence to universal character names (6.4.2).

No additional multibyte characters are supported in an identifier.

- The number of significant initial characters in an identifier (5.2.4.1, 6.4.2).

All characters in an identifier are significant.

17.3.4. Characters

- The number of bits in a byte (3.6).

There are 24 bits in a byte.

- The values of the members of the execution character set (5.2.1).

Only 24-bit characters are supported. The values of the execution character set are the same as that of the source character set. The same representation value is used for each member in the characters sets except for the escape sequences.

- The unique value of the member of the execution character set produced for each of the standard alphabetic escape sequences (5.2.2).

The following table contains an overview of the escape sequences and their byte value in the execution character set.

Escape sequence	Value
<code>\a</code>	7
<code>\b</code>	8
<code>\f</code>	12
<code>\n</code>	10
<code>\r</code>	13
<code>\t</code>	9

Escape sequence	Value
<code>\v</code>	11

- The value of a `char` object into which has been stored any character other than a member of the basic execution character set (6.2.5).

Any 24-bit value can be stored in a `char` object.

- Which of `signed char` or `unsigned char` has the same range, representation, and behavior as "plain" `char` (6.2.5, 6.3.1.1).

By default "plain" `char` is the same as specifying `signed char`. With C compiler option `--uchar (-u)` you can change the default to `unsigned char`.

- The mapping of members of the source character set (in character constants and string literals) to members of the execution character set (6.4.4.4, 5.1.1.2).

The mapping is one-to-one. The values of the execution character set are the same as that of the source character set. The same representation value is used for each member in the characters sets except for the escape sequences.

- The value of an integer character constant containing more than one character or containing a character or escape sequence that does not map to a single-byte execution character (6.4.4.4).

For any character constant containing more than one character, a warning is issued and the value is truncated to type `signed char`.

- The value of a wide character constant containing more than one multibyte character or a single multibyte character that maps to multiple members of the extended execution character set, or containing a multibyte character or escape sequence not represented in the extended execution character set (6.4.4.4).

A wide character constant can contain at most one multibyte character. Its value is represented in an `unsigned short int`. A number of wide character functions are available as C source code, but have not been compiled with the C library. To use complete wide character functionality, you must recompile the libraries with the macro `WCHAR_SUPPORT_ENABLED` and keep this macro also defined when compiling your own sources.

- The current locale used to convert a wide character constant consisting of a single multibyte character that maps to a member of the extended execution character set into a corresponding wide character code (6.4.4.4).

By default, the "C" locale is used.

- Whether differently-prefixed wide string literal tokens can be concatenated and, if so, the treatment of the resulting multibyte character sequence (6.4.5).

Differently-prefixed wide string literals can be concatenated. The encoding prefix of the first literal determines the treatment of all literals.

TASKING VX-toolset for MCS User Guide

- The current locale used to convert a wide string literal into corresponding wide character codes (6.4.5).

By default, the "C" locale is used.

- The value of a string literal containing a multibyte character or escape sequence not represented in the execution character set (6.4.5).

All source characters can be represented in the execution character set.

- The encoding of any of `wchar_t`, `char16_t`, and `char32_t` where the corresponding standard encoding macro (`__STDC_ISO_10646__`, `__STDC_UTF_16__`, or `__STDC_UTF_32__`) is not defined (6.10.8.2).

The MCS compiler implements these typedefs with the following types:

Typedef	Implementation
<code>wchar_t</code>	unsigned short
<code>char16_t</code>	unsigned char
<code>char32_t</code>	unsigned long

17.3.5. Integers

- Any extended integer types that exist in the implementation (6.2.5).

All types are described in [Section 1.1, Data Types](#).

- Whether signed integer types are represented using sign and magnitude, two's complement, or ones' complement, and whether the extraordinary value is a trap representation or an ordinary value (6.2.6.2).

Signed integer types are represented in two's complement. The most significant bit is the sign bit. 1 is negative, 0 is positive.

- The rank of any extended integer type relative to another extended integer type with the same precision (6.3.1.1).

All types are described in [Section 1.1, Data Types](#).

- The result of, or the signal raised by, converting an integer to a signed integer type when the value cannot be represented in an object of that type (6.3.1.3).

At compile time, when converting integer types and a value does not fit in a type, the compiler issues a warning and the value is truncated. At run-time no warning or signal is given and the value is truncated.

- The results of some bitwise operations on signed integers (6.5).

The result of `E1>>E2` is E1 right shifted E2 bit positions. If E1 has a signed type and a negative value, the shift behavior is implemented as an arithmetic shift. The empty position in the most significant bit is filled with a copy of the original most significant bit.

17.3.6. Floating-Point

- The accuracy of the floating-point operations and of the library functions in `<math.h>` and `<complex.h>` that return floating-point results (5.2.4.2.2).

A float has 24 significant mantissa bits and 8 exponent bits. A double or long double has 53 significant mantissa bits and 11 exponent bits. This is conform IEEE-754 for single precision and double precision floating-point. Internally the compiler uses a mantissa of 80 bits. The results of floating-point operations are rounded to the nearest IEEE-754 format.

The accuracy of `sqrt` is defined unknown.

- The accuracy of the conversions between floating-point internal representations and string representations performed by the library functions in `<stdio.h>`, `<stdlib.h>`, and `<wchar.h>` (5.2.4.2.2).

The accuracy of the conversions is unknown.

- The rounding behaviors characterized by non-standard values of `FLT_ROUNDS` (5.2.4.2.2).

No non-standard values are used.

- The evaluation methods characterized by non-standard negative values of `FLT_EVAL_METHOD` (5.2.4.2.2).

`FLT_EVAL_METHOD` is defined as 0. No non-standard values are used.

- The direction of rounding when an integer is converted to a floating-point number that cannot exactly represent the original value (6.3.1.4).

The round to nearest method is used. `FLT_ROUNDS` is ignored.

- The direction of rounding when a floating-point number is converted to a narrower floating-point number (6.3.1.5).

The round to nearest method is used. `FLT_ROUNDS` is ignored.

- How the nearest representable value or the larger or smaller representable value immediately adjacent to the nearest representable value is chosen for certain floating constants (6.4.4.2).

The round to nearest method is used. `FLT_ROUNDS` is ignored.

- Whether and how floating expressions are contracted when not disallowed by the `FP_CONTRACT` pragma (6.5).

Pragma `FP_CONTRACT` is equivalent to **compiler option `--fp-model=+contract`**. This has only effect for fused multiply-and-accumulate (FMA) operations. FMA operations are not supported by the IEEE 754-1985 standard. The result of FMA operations is only rounded once at the end of the FMA. You can disable FMAs with the **compiler option `--fp-model=-contract`**.

- The default state for the `FENV_ACCESS` pragma (7.6.1).

The default state of pragma `FENV_ACCESS` is "off". This pragma is ignored.

TASKING VX-toolset for MCS User Guide

- Additional floating-point exceptions, rounding modes, environments, and classifications, and their macro names (7.6, 7.12).

No additional floating-point exceptions, rounding modes, environments, and classifications are defined.

- The default state for the `FP_CONTRACT` pragma (7.12.2).

The default state of pragma `FP_CONTRACT` is set by the **contract** flag of [compiler option `--fp-model`](#). The default state is "on".

17.3.7. Arrays and Pointers

- The result of converting a pointer to an integer or vice versa (6.3.2.3).

All non-pointer conversions to and from a 24-bit pointer are implemented as a conversion to or from a 24-bit integer type.

- The size of the result of subtracting two pointers to elements of the same array (6.5.6).

The size of `ptrdiff_t` is 24 bits. The difference in address location is expressed in bytes.

17.3.8. Hints

- The extent to which suggestions made by using the `register` storage-class specifier are effective (6.7.1).

The compiler does not make assumptions based on the `register` storage-class specifier. So, basically this keyword is ignored, except that you cannot take the address of a `register` variable. The compiler issues an error in that case.

- The extent to which suggestions made by using the `inline` function specifier are effective (6.7.4).

With the `inline` keyword you force the compiler to inline the specified function, regardless of the optimization strategy of the compiler itself. For more information see [Section 1.9.5, *Inlining Functions: inline*](#).

17.3.9. Structures, Unions, Enumerations, and Bit-fields

- Whether a "plain" `int` bit-field is treated as a signed `int` bit-field or as an unsigned `int` bit-field (6.7.2, 6.7.2.1).

By default an `int` bit-field is treated as unsigned `int`. This offers the best performance. With [C compiler option `--signed-bitfields`](#) you tell the compiler to treat `int` bit-fields as signed `int`. In this case, you can still add the keyword `unsigned` to treat a particular `int` bit-field as unsigned.

- Allowable bit-field types other than `_Bool`, signed `int`, and unsigned `int` (6.7.2.1).

The integer types signed `char`, unsigned `char`, signed `short` and unsigned `short` as specified in [Section 1.1, *Data Types*](#), are also allowable bit-field types.

- Whether atomic types are permitted for bit-fields (6.7.2.1).

Atomic types are not permitted for bit-fields.

- Whether a bit-field can straddle a storage-unit boundary (6.7.2.1).

A bit-field cannot straddle a storage-unit boundary. If insufficient space remains, the bit-field is put into the next unit.

- The order of allocation of bit-fields within a unit (6.7.2.1).

Allocation starts at the least significant bit up to the most significant bit. If the following bit-field fits within the same unit, it is allocated starting at the next available bit.

- The alignment of non-bit-field members of structures (6.7.2.1). This should present no problem unless binary data written by one implementation is read by another.

The alignment of non-bit-field members of structures is the same as the alignment for data types as specified in [Section 1.1, Data Types](#).

- The integer type compatible with each enumerated type (6.7.2.2).

The compiler always uses `int` for enumeration.

17.3.10. Qualifiers

- What constitutes an access to an object that has `volatile`-qualified type (6.7.3).

Any reference to an object with `volatile` type results in an access. The order in which `volatile` objects are accessed is defined by the order expressed in the source code. References to non-`volatile` objects are scheduled in arbitrary order, within the constraints given by dependencies.

If the [compiler option `--language=+volatile \(-Av\)`](#) is set, all references to non-`volatile` objects result in an access before the access to a `volatile` object that occurs subsequently in the source file takes place. The `volatile` access acts as a memory barrier.

17.3.11. Preprocessing Directives

- The locations within `#pragma` directives where header name preprocessing tokens are recognized (6.4, 6.4.7).

Within a `#pragma` directive, header name preprocessing tokens are not recognized.

- How sequences in both forms of header names are mapped to headers or external source file names (6.4.7).

Sequences in header names are mapped to file names as is. The backslash `"\"` is not interpreted as an escape sequence. The backslash `"\"` (Windows) or forward slash `"/"` (Windows and UNIX) is interpreted as a standard directory separator.

TASKING VX-toolset for MCS User Guide

- Whether the value of a character constant in a constant expression that controls conditional inclusion matches the value of the same character constant in the execution character set (6.10.1).

A character constant in a constant expression that controls conditional inclusion matches the value of the same character constant in the execution character set.

- Whether the value of a single-character character constant in a constant expression that controls conditional inclusion may have a negative value (6.10.1).

A single-character character constant in a constant expression that controls conditional inclusion may have a negative value.

- The places that are searched for an included `< >` delimited header, and how the places are specified or the header is identified (6.10.2).

How the compiler searches for include files is explained in [Section 3.3, *How the Compiler Searches Include Files*](#).

- How the named source file is searched for in an included `" "` delimited header (6.10.2).

How the compiler searches for include files is explained in [Section 3.3, *How the Compiler Searches Include Files*](#).

- The method by which preprocessing tokens (possibly resulting from macro expansion) in a `#include` directive are combined into a header name (6.10.2).

Preprocessing tokens in a `#include` directive are combined the same way as outside a `#include` directive.

- The nesting limit for `#include` processing (6.10.2).

There is no nesting limit for `#include` processing.

- Whether the `#` operator inserts a `\` character before the `\` character that begins a universal character name in a character constant or string literal (6.10.3.2).

The `#` operator inserts a `\` character before every `\` character in a character constant or string literal.

- The behavior on each recognized non-STDC `#pragma` directive (6.10.6).

All non-STDC pragmas are described in [Section 1.7, *Pragmas to Control the Compiler*](#).

- The definitions for `__DATE__` and `__TIME__` when respectively, the date and time of translation are not available (6.10.8.1).

The date and time of translation are always available, macros `__DATE__` and `__TIME__` are always defined.

17.3.12. Library Functions

- Any library facilities available to a freestanding program, other than the minimal set required by clause 4 (5.1.2.1).

All library functions are described in [Chapter 10, Libraries](#). Some functions are not completely implemented because their implementation depends on the context where your application will run. These functions are for example all I/O related functions. Where possible, these functions are implemented using file system simulation (FSS). This system can be used by the debugger to simulate an I/O environment which enables you to debug your application. If the application runs under control of the debugger and FSS is used, then the low-level behavior is equal to the host system's file access behavior.

In the implementation in the C library, the basic sequences of a multibyte character consist of single bytes (`MB_LEN_MAX` is set to 1). If you want full multibyte support, you need to change the C library. See the notes in the header files `stdio.h` and `wchar.h` for more information.

- The format of the diagnostic printed by the `assert` macro (7.2.1.1).

The `assert()` function is implemented as a macro in `assert.h`. The output is:

```
Assertion failed: (expression) file filename, line linenumber
```

when the parameter evaluates to zero.

- The representation of the floating-point status flags stored by the `fegetexceptflag` function (7.6.2.2).

Exception flags are supported and are defined in header file `fenv.h`:

```
#define FE_DIVBYZERO    (1 << 1)
#define FE_INEXACT     (1 << 2)
#define FE_INVALID     (1 << 3)
#define FE_OVERFLOW    (1 << 4)
#define FE_UNDERFLOW  (1 << 5)
```

- Whether the `feraiseexcept` function raises the "inexact" floating-point exception in addition to the "overflow" or "underflow" floating-point exception (7.6.2.3).

Function `feraiseexcept` does not raise `FE_INEXACT` if underflow or overflow is raised.

- Strings other than "C" and "" that may be passed as the second argument to the `setlocale` function (7.11.1.1).

No other strings are predefined. A NULL pointer as the second argument returns the "C" locale. Any other string than "C" or "" can be passed as the second argument to the `setlocale` function and results in NULL.

- The types defined for `float_t` and `double_t` when the value of the `FLT_EVAL_METHOD` macro is less than 0 (7.12).

The `FLT_EVAL_METHOD` macro can only have the values 0, 1 or 2.

TASKING VX-toolset for MCS User Guide

- Domain errors for the mathematical functions, other than those required by this International Standard (7.12.1).

No other domain errors exist, other than those required by the standard.

- The values returned by the mathematical functions on domain errors or pole errors (7.12.1).

On domain errors (`errno` is set to `EDOM`), the mathematical functions return a value as specified in the following table.

Math function	Return value on EDOM
<code>acos(x > 1.0)</code>	0.0
<code>asin(x > 1.0)</code>	0.0
<code>log(x < 0.0)</code>	-HUGE_VAL
<code>pow(x <= 0.0)</code>	0.0
<code>sqrt(x < 0.0)</code>	-NaN

- The values returned by the mathematical functions on underflow range errors, whether `errno` is set to the value of the macro `ERANGE` when the integer expression `math_errhandling & MATH_ERRNO` is nonzero, and whether the "underflow" floating-point exception is raised when the integer expression `math_errhandling & MATH_ERREXCEPT` is nonzero. (7.12.1).

On underflow range errors, the mathematical functions return 0.0. `math_errhandling` is set to `MATH_ERRNO`. `errno` is not set to `ERANGE` on underflow range errors

- Whether a domain error occurs or zero is returned when an `fmod` function has a second argument of zero (7.12.10.1).

Zero (0.0) is returned when an `fmod` function has a second argument of zero.

- Whether a domain error occurs or zero is returned when a remainder function has a second argument of zero (7.12.10.2).

A domain error occurs.

- The base-2 logarithm of the modulus used by the `remquo` functions in reducing the quotient (7.12.10.3).

The `remquo` function calculates at least 8 bits of the quotient.

- Whether a domain error occurs or zero is returned when a `remquo` function has a second argument of zero (7.12.10.3).

A domain error occurs.

- Whether the equivalent of `signal(sig, SIG_DFL);` is executed prior to the call of a signal handler, and, if not, the blocking of signals that is performed (7.14.1.1).

The equivalent of `signal(sig, SIG_DFL);` is executed prior to the call of a signal handler.

- The null pointer constant to which the macro `NULL` expands (7.19).

Macro `NULL` is defined as `(void *) 0`.

- Whether the last line of a text stream requires a terminating new-line character (7.21.2).

Both a new-line character (`\n`) and end-of-file (`EOF`) are recognized as the termination character of a line.

- Whether space characters that are written out to a text stream immediately before a new-line character appear when read in (7.21.2).

Space characters written to a stream immediately before a new-line character are preserved.

- The number of null characters that may be appended to data written to a binary stream (7.21.2).

I/O related functions are implemented using file system simulation (FSS). This system can be used by the debugger to simulate an I/O environment. If the application runs under control of the debugger and FSS is used, then the low-level behavior is equal to the host system's file access behavior. The library does not append any null characters. It depends on the `open()` function on the host environment what happens. You can write your own `_open()` function if necessary.

- Whether the file position indicator of an append-mode stream is initially positioned at the beginning or end of the file (7.21.3).

I/O related functions are implemented using file system simulation (FSS). This system can be used by the debugger to simulate an I/O environment. If the application runs under control of the debugger and FSS is used, then the low-level behavior is equal to the host system's file access behavior. Where the file position indicator of an append-mode stream is initially positioned depends on the `open()` function on the host environment. You can write your own `_open()` function if necessary.

- Whether a write on a text stream causes the associated file to be truncated beyond that point (7.21.3).

I/O related functions are implemented using file system simulation (FSS). This system can be used by the debugger to simulate an I/O environment. If the application runs under control of the debugger and FSS is used, then the low-level behavior is equal to the host system's file access behavior. Whether a write on a text stream causes the associated file to be truncated beyond that point depends on how the low-level file routines are implemented in your application.

- The characteristics of file buffering (7.21.3).

Files can be unbuffered, fully buffered or line buffered. What actually happens depends on how the low-level file routines are implemented in your application.

- Whether a zero-length file actually exists (7.21.3).

This depends on how the low-level file routines are implemented in your application.

- The rules for composing valid file names (7.21.3).

This depends on how the low-level file routines are implemented in your application.

TASKING VX-toolset for MCS User Guide

- Whether the same file can be simultaneously open multiple times (7.21.3).
This depends on how the low-level file routines are implemented in your application.
- The nature and choice of encodings used for multibyte characters in files (7.21.3).
Use of variable length encoded characters in files in comments and string literals is permitted.
- The effect of the `remove` function on an open file (7.21.4.1).
This depends on how the low-level file routines are implemented in your application.
- The effect if a file with the new name exists prior to a call to the `rename` function (7.21.4.2).
This depends on how the low-level file routines are implemented in your application.
- Whether an open temporary file is removed upon abnormal program termination (7.21.4.3).
This depends on how the low-level file routines are implemented in your application.
- Which changes of mode are permitted (if any), and under what circumstances (7.21.5.4).
The `freopen()` function first calls `fclose()` and then calls `_fopen()` with the new mode.
- The style used to print an infinity or NaN, and the meaning of any `n-char` or `n-wchar` sequence printed for a NaN (7.21.6.1, 7.29.2.1).
The style used to print an infinity or NaN is `inf` and `nan` respectively (`INF` or `NAN` for the `F` conversion specifier). `n-char` or `n-wchar` sequences are not used for `nan`.
- The output for `%p` conversion in the `fprintf` or `fwprintf` function (7.21.6.1, 7.29.2.1).
The argument is treated as having type `void *`. The value will be printed as a hexadecimal value, similar to `%x`.
- The interpretation of a `-` character that is neither the first nor the last character, nor the second where a `^` character is the first, in the scanlist for `%[` conversion in the `fscanf` or `fwscanf` function (7.21.6.2, 7.29.2.1).
A `-` character is treated as a normal character.
- The set of sequences matched by a `%p` conversion and the interpretation of the corresponding input item in the `fscanf` or `fwscanf` function (7.21.6.2, 7.29.2.2).
The format of `%p` matches the format of `%x`. The input for `%p` is a hexadecimal value, which is converted to a value with type `void *`.
- The value to which the macro `errno` is set by the `fgetpos`, `fsetpos`, or `ftell` functions on failure (7.21.9.1, 7.21.9.3, 7.21.9.4).
If `errno` is set to a value depends on how the low-level file routines are implemented in your application.

- The meaning of any `n-char` or `n-wchar` sequence in a string representing a NaN that is converted by the `strtod`, `strtof`, `strtold`, `wcstod`, `wcstof`, or `wcstold` function (7.22.1.3, 7.29.4.1.1).

An `n-char` or `n-wchar` sequence in a string representing a NaN is ignored.

- Whether or not the `strtod`, `strtof`, `strtold`, `wcstod`, `wcstof`, or `wcstold` function sets `errno` to `ERANGE` when underflow occurs (7.22.1.3, 7.29.4.1.1).

`errno` is set to `ERANGE` when underflow occurs and the value returned is 0.0.

- Whether the `calloc`, `malloc`, and `realloc` functions return a null pointer or a pointer to an allocated object when the size requested is zero (7.22.3).

`NULL` is returned when a size of zero is requested.

- Whether open streams with unwritten buffered data are flushed, open streams are closed, or temporary files are removed when the `abort` or `_Exit` function is called (7.22.4.1, 7.22.4.4).

When the `abort()` or `_Exit()` function is called, open streams with unwritten buffered data are not flushed, open streams are not closed, and temporary files are not removed.

- The termination status returned to the host environment by the `abort`, `exit`, `_Exit`, or `quick_exit` function (7.22.4.1, 7.22.4.4, 7.22.4.5, 7.22.4.7).

`abort()` calls `_Exit()` with `EXIT_FAILURE`.

`exit()` and `quick_exit` call `_Exit()` with their input value.

`_Exit()` returns the input value to the host environment.

- The value returned by the `system` function when its argument is not a null pointer (7.22.4.6).

A skeleton is provided for the `system()` function in the C library, because the embedded environment has no operating system. The `system()` function returns the value 0.

- The range and precision of times representable in `clock_t` and `time_t` (7.27).

`clock_t` is defined as `unsigned long long`, `time_t` is defined as `unsigned long`. The resolution of the clock is defined by `CLOCKS_PER_SEC`, which is set by means of the C startup code (see the `setclockpersec()` function in `cstart.c`).

- The local time zone and Daylight Saving Time (7.27.1).

The default time zone is UTC. Daylight Saving Time is not available (`tm_isdst=-1`).

- The era for the `clock` function (7.27.2.1).

The `clock` function returns the current processor time.

- The `TIME_UTC` epoch (7.27.2.5).

The `timespec_get()` function is based on the `clock()` function. Therefore, the epoch is the starting time of the `clock()` function.

TASKING VX-toolset for MCS User Guide

- The replacement string for the %Z specifier to the `strftime`, and `wcsftime` functions in the "C" locale (7.27.3.5, 7.29.5.1).

%Z is replaced by the time zone name, by default UTC.

- Whether the functions in `<math.h>` honor the rounding direction mode in an IEC 60559 conformant implementation, unless explicitly specified otherwise (F.10).

The round to nearest method is used. `FLT_ROUNDS` is defined as 1.

17.3.13. Architecture

- The values or expressions assigned to the macros specified in the headers `<float.h>`, `<limits.h>`, and `<stdint.h>` (5.2.4.2, 7.20.2, 7.20.3).

Macros in `<float.h>`:

Macro <code><float.h></code>	Value
<code>FLT_RADIX</code>	2
<code>FLT_ROUNDS</code>	1 (round to nearest)
<code>FLT_EVAL_METHOD</code>	0
<code>FLT_MANT_DIG</code>	24
<code>FLT_DIG</code>	6
<code>FLT_EPSILON</code>	1.19209290E-07F
<code>FLT_MIN</code>	1.17549435E-38F
<code>FLT_MIN_EXP</code>	-125
<code>FLT_MIN_10_EXP</code>	-37
<code>FLT_MAX</code>	3.40282347E+38F
<code>FLT_MAX_EXP</code>	+128
<code>FLT_MAX_10_EXP</code>	+38
<code>[L]DBL_MANT_DIG</code>	53
<code>[L]DBL_DIG</code>	15
<code>[L]DBL_EPSILON</code>	2.2204460492503131E-16
<code>[L]DBL_MIN</code>	2.2250738585072014E-308
<code>[L]DBL_MIN_EXP</code>	-1021
<code>[L]DBL_MIN_10_EXP</code>	-307
<code>[L]DBL_MAX</code>	1.7976931348623157E+308
<code>[L]DBL_MAX_EXP</code>	+1024
<code>[L]DBL_MAX_10_EXP</code>	+308
<code>DECIMAL_DIG</code>	17 (for double FP), 9 (for single FP)

Macros in `<limits.h>`:

Macro <code><limits.h></code>	Value
CHAR_BIT	24
SCHAR_MIN	-SCHAR_MAX-1
SCHAR_MAX	0x7fffff
UCHAR_MAX	0xfffffU
CHAR_MIN	__CHAR_MIN (min value of 'plain' char)
CHAR_MAX	__CHAR_MAX (max value of 'plain' char)
MB_LEN_MAX	1
SHRT_MIN	-SHRT_MAX-1
SHRT_MAX	0x7ffff
USHRT_MAX	0xfffffU
INT_MIN	-INT_MAX-1
INT_MAX	0x7ffff
UINT_MAX	0xfffffU
LONG_MIN	-LONG_MAX-1
LONG_MAX	0x7fffffffffL
ULONG_MAX	0xfffffffffUL
LLONG_MIN	-LLONG_MAX-1
LLONG_MAX	0x7fffffffffffffffLL
ULLONG_MAX	0xffffffffffffffffULL

The limit macros in `<stdint.h>` for exact-width, minimum-width and fastest-width integer types have the same ranges as `char`, `short`, `int`, `long` and `long long`. Furthermore the following macros are defined:

Macro <code><stdint.h></code>	Value
INTPTR_MIN	INT24_MIN
INTPTR_MAX	INT24_MAX
UINTPTR_MAX	UINT24_MAX
INTMAX_MIN	INT72_MIN
INTMAX_MAX	INT72_MAX
UINTMAX_MAX	UINT72_MAX
PTRDIFF_MIN	__PTRDIFF_MIN
PTRDIFF_MAX	__PTRDIFF_MAX
SIG_ATOMIC_MIN	INT24_MIN
SIG_ATOMIC_MAX	INT24_MAX

Macro <stdint.h>	Value
SIZE_MAX	__SIZE_MAX
WCHAR_MIN	__WCHAR_MIN
WCHAR_MAX	__WCHAR_MAX
WINT_MIN	0
WINT_MAX	UINT24_MAX

- The result of attempting to indirectly access an object with automatic or thread storage duration from a thread other than the one with which it is associated (6.2.4).

Threads are not supported (`__STDC_NO_THREADS__ = 1`).

- The number, order, and encoding of bytes in any object (when not explicitly specified in this International Standard) (6.2.6.1).

All types are described in [Section 1.1, Data Types](#).

- Whether any extended alignments are supported and the contexts in which they are supported (6.2.8).

For statically allocated objects, extended alignments greater than or equal to 8 are supported.

- Valid alignment values other than those returned by an `_Alignof` expression for fundamental types, if any (6.2.8).

Any nonnegative integral power of two can be used as additional alignment value.

- The value of the result of the `sizeof` and `_Alignof` operators (6.5.3.4).

The values of the size and alignment of the data types are described in [Section 1.1, Data Types](#). Divide the size by 24 to get the values for the `sizeof` operator. Divide the alignment by 8 to get the values for the `_Alignof` operator.

17.4. C11 Locale-specific Behavior

Locale-specific behavior is behavior that depends on local conventions of nationality, culture, and language that each implementation documents.

The following items describe the locale-specific characteristics, as indicated in Annex J.4 of the ISO/IEC 9899:2011 (E) standard.

- Additional members of the source and execution character sets beyond the basic character set (5.2.1).

The compiler accepts all one-byte characters in the host's default character set. Use of variable length encoded characters in the source file in comments and string literals is permitted.

In the implementation in the C library, the basic sequences of a multibyte character consist of single bytes (`MB_LEN_MAX` is set to 1). If you want full multibyte support, you need to change the C library. See the notes in the header files `stdio.h` and `wchar.h` for more information.

- The presence, meaning, and representation of additional multibyte characters in the execution character set beyond the basic character set (5.2.1.2).

Use of variable length encoded characters in the source file in comments and string literals is permitted.

- The shift states used for the encoding of multibyte characters (5.2.1.2).

A multibyte character must be a single byte when in the initial shift state.

- The direction of writing of successive printing characters (5.2.2).

The direction of writing depends on the application and the display device.

- The decimal-point character (7.1.1).

The default decimal-point character is a '.'.

- The set of printing characters (7.4, 7.30.2).

The set of printing characters are the characters for which the `isprint()` function returns true. Printing characters are characters in the range 32 (space) to 126.

- The set of control characters (7.4, 7.30.2).

The set of control characters are the characters for which the `iscntrl()` function returns true. Control characters are characters in the range 0 to 31 and 127.

- The sets of characters tested for by the `isalpha`, `isblank`, `islower`, `ispunct`, `isspace`, `isupper`, `iswalpha`, `iswblank`, `iswlower`, `iswpunct`, `iswspace`, or `iswupper` functions (7.4.1.2, 7.4.1.3, 7.4.1.7, 7.4.1.9, 7.4.1.10, 7.4.1.11, 7.30.2.1.2, 7.30.2.1.3, 7.30.2.1.7, 7.30.2.1.9, 7.30.2.1.10, 7.30.2.1.11).

The characters tested for are specified in the following table.

Function	Characters tested
<code>isalpha</code>	a-z, A-Z
<code>isblank</code>	' ' (space), '\t' (tab)
<code>islower</code>	a-z
<code>ispunct</code>	!, ", #, \$, %, &, ', (,), *, +, ,, -, ., /, :, ;, <, =, >, ?, @, [, \,], ^, _ , ` , {, , }, ~
<code>isspace</code>	' ' (space), '\t', '\n', '\v', '\f', '\r'
<code>isupper</code>	A-Z

- The native environment (7.11.1.1).

The native environment is the same as the "C" locale.

- Additional subject sequences accepted by the numeric conversion functions (7.22.1, 7.29.4.1).

No additional subject sequences are accepted.

TASKING VX-toolset for MCS User Guide

- The collation sequence of the execution character set (7.24.4.3, 7.29.4.4.2).

Only the "C" locale is supported. The `strcoll()` function is the same as the `strcmp()` function. The `wscoll()` function is the same as the `wcscmp()` function.

- The contents of the error message strings set up by the `strerror` function (7.24.6.2).

The error message strings returned by `strerror()` depend on the argument. Typically, the values for the argument come from `errno.h`. For a list of messages see [Section 10.1.5, *errno.h*](#).

- The formats for time and date (7.27.3.5, 7.29.5.1).

English names for months and days are used.

`%c` is replaced by the following date and time representation: `%a %b %e %H:%M:%S %Y`

`%x` is replaced by the following date representation: `%m/%d/%y`

`%X` is replaced by the following time representation: `%H:%M:%S`

- Character mappings that are supported by the `towctrans` function (7.30.1).

The character mappings supported by the `towctrans()` function are defined in `wctype.h`: `_to_lower` and `_to_upper`.

- Character classifications that are supported by the `iswctype` function (7.30.1).

The character classifications supported by the `iswctype()` function are defined in `wctype.h`: `_alnum`, `_alpha`, `_cntrl`, `_digit`, `_graph`, `_lower`, `_print`, `_punct`, `_space`, `_upper`, `_xdigit` and `_blank`.
